Mathematical Modeling of Physical Systems

3D Mechanics

- We shall now look at a second application of multi-bond graphs: *3D mechanics*.
- 3D mechanical models look superficially just like planar mechanical models. There are additional types of joints, but other than that, there seem to be few surprises.
- Yet, the seemingly similar appearance is deceiving. There are a substantial number of complications that the modeler has to cope with when dealing with 3D mechanics. These are the subject of this lecture.

Mathematical Modeling of Physical Systems

Degrees of Freedom

- 1D mechanical systems exhibit exactly one degree of freedom (either translational or rotational).
- 2D mechanical systems have three degrees of freedom. They can translate along two axes, and they can rotate around an axis that is perpendicular to the plane spanned by the two translational axes.
- 3D mechanical systems allow six degrees of freedom. They can translate along three spatial axes, and they can rotate around each of those three axes as well.

3D Mechanical Multi-bonds

- Consequently, the 3D mechanical multi-bonds are expected to contain six parallel regular bonds, one for each degree of freedom:

3D Mechanical Connectors

- The 3D mechanical multi-bond connectors should carry 13 variables, an effort vector, \mathbf{e} , of length 6, a flow vector, \mathbf{f} , also of length 6, plus the directional variable, d .
- The 3D mechanical multi-body connectors would need to carry 18 variables, namely 12 potential variables describing the 6 generalized positions and the 6 generalized velocities, and 6 flow variables describing the generalized forces.
- In reality, they carry 24 variables, as shown on the next slide.

Mathematical Modeling of Physical Systems

The Body-fixed Coordinate System

- In 3D mechanics, the inertial tensor depends on the orientation of the body relative to its coordinate system.
- Hence, if the *world coordinate system* is being used for formulating the d'Alembert principle for rotational motion, the inertial tensor must be constantly updated.
- Alternatively, we can formulate the d'Alembert principle in a *body-fixed coordinate system*. In this way, the inertial tensor remains constant.
- However, we now must calculate the relative coordinate transformations across joints.
- We must also take into account the *gyroscopic torques* that result from formulating the d'Alembert principle in an accelerated frame.

Mathematical Modeling of Physical Systems

The Body-fixed Coordinate System II

- In planar mechanics, this wasn't a problem yet. There is a single axis of rotation that is always perpendicular to the plane of translation.
- Consequently, the inertia remains constant, and we can (and have been) calculating all motions in the world coordinate system.
- This fact makes planar mechanics considerably simpler and more easy to understand than 3D mechanics.

November 15, 2012

Start Presentation

The Orientation Matrix

- The orientation matrix, R , is a *unitary matrix*.
- Hence:

$$\|R\|_2 = 1$$

$$R^{-1} = R^T$$

- Each row vector and each column vector of R is of length 1, hence there are 6 constraint equations connecting the 9 matrix elements.
- As expected, there are only 3 degrees of freedom, describing the relative rotation of one coordinate system to another.

Coordinate Transformations

- Coordinate transformations can be interpreted as an act of transformation in a bond graph sense:

$$\underline{\omega}_2 = R \cdot \underline{\omega}_1$$

$$\Rightarrow \underline{\tau}_1 = R^T \cdot \underline{\tau}_2$$

November 15, 2012

© Prof. Dr. François E. Cellier

Start Presentation

Coordinate Transformations II

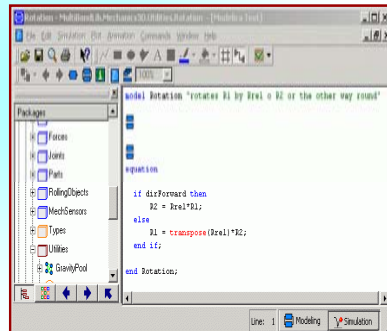

- We must separately also transform the angular positions:

$$\underline{\omega}_2 = R_{rel} \cdot \underline{\omega}_1$$

$$\Rightarrow \underline{\varphi}_2 = R_{rel} \cdot \underline{\varphi}_1$$

$$R_2 = R_{rel} \cdot R_1$$

November 15, 2012

© Prof. Dr. François E. Cellier

Start Presentation

Efficient Simulation Equations

$$R_2 = R_{rel} \cdot R_1$$

$$\Rightarrow R_1 = R_{rel}^{-1} \cdot R_2 = R_{rel}^T \cdot R_2$$

- Dymola* doesn't understand the concept of a *unitary matrix*.
- Hence, if the computational causality requires an inversion of the R matrix, that is what *Dymola* will provide ... in symbolic form.
- This leads to highly inefficient equations at run time.
- Thus, it is better to help *Dymola* by specifying the direction of computational flow explicitly.

Computation of Orientation Matrix

- One way to compute the orientation matrix, R , in a non-redundant fashion is by means of **Cardan angles**. These are the angles of rotation around the Cartesian coordinates: φ_x , φ_y , and φ_z .

$$R_x = \begin{pmatrix} 1 & 0 & 0 \\ 0 & \cos(\varphi_x) & \sin(\varphi_x) \\ 0 & -\sin(\varphi_x) & \cos(\varphi_x) \end{pmatrix}$$

$$R_y = \begin{pmatrix} \cos(\varphi_y) & 0 & -\sin(\varphi_y) \\ 0 & 1 & 0 \\ \sin(\varphi_y) & 0 & \cos(\varphi_y) \end{pmatrix}$$

$$R_z = \begin{pmatrix} \cos(\varphi_z) & \sin(\varphi_z) & 0 \\ -\sin(\varphi_z) & \cos(\varphi_z) & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

$$\Rightarrow R = R_z \cdot R_y \cdot R_x$$

- Whereas R can always be computed out of φ_x , φ_y , and φ_z in a unique fashion, the opposite is unfortunately not true.
- If $\varphi_y = 90^\circ$, the other two axes are aligned, and φ_x and φ_z cannot be determined in a unique fashion.
- Hence **Cardan angles** are not always a good choice.

Computation of Orientation Matrix III

- Any 3D rotation can be expressed as a **planar rotation**, φ , perpendicular to a translational plane, n .
- Given the rotation angle, φ , and the translational plane, n , the orientation matrix can be computed as follows:

$$R = n \cdot n^T + (I - n \cdot n^T) \cos(\varphi) - \tilde{N} \sin(\varphi)$$

- where:

$$\tilde{N} = \begin{bmatrix} 0 & -n_3 & n_2 \\ n_3 & 0 & -n_1 \\ -n_2 & n_1 & 0 \end{bmatrix}$$

$$(a \times b = \tilde{A} \cdot b)$$

November 15, 2012

© Prof. Dr. François E. Cellier

Start Presentation

Computation of Orientation Matrix IV

$$R = n \cdot n^T + (I - n \cdot n^T) \cos(\varphi) - \tilde{N} \sin(\varphi)$$

- Unfortunately, also the planar rotation method is not always invertible in a unique fashion. A null rotation does not have a well defined axis of rotation. Hence, this method should only be used if the axis of rotation is always known, as in a revolute joint.

Mathematical Modeling of Physical Systems

Quaternions

- A redundant way of describing orientation that works in all situations is by means of *quaternions*.
- Quaternions are a four-dimensional extension to complex numbers:

$$Q = c + ui + vj + wk = c + u$$
- Quaternions are characterized by the three imaginary components, *i*, *j*, and *k* that satisfy the following computational rules:

$$\begin{array}{lll} ij = k; & ji = -k; & i^2 = -1 \\ jk = i; & kj = -i; & j^2 = -1 \\ ki = j; & ik = -j; & k^2 = -1 \end{array}$$

Mathematical Modeling of Physical Systems

Quaternions II

- The product of two quaternions can be written as:

$$QQ' = (c + u)(c' + u') = (cc' - u \cdot u') + (u \times u') + cu' + c'u$$
- The complement of a quaternion is being defined as:

$$\bar{Q} = c + \bar{u} = c - u$$
- The norm of a quaternion is the product of the quaternion with its complement:

$$Q\bar{Q} = |Q| = c^2 + |u|^2$$
- A unit quaternion is a quaternion with norm 1:

$$|Q| = c^2 + |u|^2 = 1$$

Mathematical Modeling of Physical Systems

Quaternions III

- In accordance with trigonometry:

$$\cos(\varphi/2)^2 + \sin(\varphi/2)^2 = 1$$

it is always possible to find an angle φ such that:

$$c = \cos(\varphi/2); \quad |u| = \sin(\varphi/2)$$
- This enables us to encode the orientation of a coordinate system as a quaternion, whereby the axis of rotation is encoded as *u*, where $[u, v, w]^T$ is being interpreted as a vector pointing in the direction of the axis of rotation. The fourth quantity, *c*, of the quaternion encodes the angle of rotation, φ .
- Then:

$$R = 2u \cdot u^T + 2c\bar{U} + 2c^2I - I$$

Mathematical Modeling of Physical Systems

Computation of Orientation Matrix V

$$R = 2u \cdot u^T + 2c\bar{U} + 2c^2I - I$$

- The multi-bond graph library uses all three representations. It uses the *planar rotation* method inside revolute joints, and either *Cardan angles* or *quaternions* (user's choice) within more general joints, such as the spherical joints.

Start Presentation

The Wrapper Models

- In the multi-bond graph library, the equations of motion are formulated in the world coordinate system for translational motions, and in a body-fixed coordinate system for rotational motions.
- For this reason, the bond graphs for translational and rotational motions are kept separate from each other, and the 3D mechanics multi-bonds have therefore still a cardinality of 3.

Equations of Motion in Body System

- Let us formulate the *equations of motion* in a *body-fixed coordinate system*:

$$\tau_0 = J_0 \cdot \dot{\omega}_0$$

$$\Rightarrow \tau_0 = \frac{d}{dt} (R^T J_{body} \omega_{body})$$

$$\Rightarrow \tau_0 = R^T J_{body} \dot{\omega}_{body} + \dot{R}^T J_{body} \omega_{body}$$

$$\Rightarrow R^T \tau_{body} = R^T J_{body} \dot{\omega}_{body} + R^T \dot{J}_{body} \omega_{body}$$

$$\Rightarrow \tau_{body} = J_{body} \dot{\omega}_{body} + \omega_{body} \times J_{body} \omega_{body}$$

Gyroscopic torque

The Model of a Body

- We are now ready to model a general body using the multi-bond graph library:

- The translational equations of motion are formulated in world coordinates.
- The rotational equations of motion are formulated in body-fixed coordinates.
- The gravitational pool is computed by the world model of wrapped 3D mechanics.

Mathematical Modeling of Physical Systems

The Model of a Body VI

```

equation
  if GFIndex > 0 then
    world3D.gravityPos(GFIndex, i) = frame_a.P.x;
    world3D.gravityPos(GFIndex) = a;
  end if;
  gf = use1430.gravityPos.gravityForce(GFIndex);
  adf1.s = a*use1430.gravityAcceleration(Mech27861, i) * gf;
end Body;

```

- The center of the gravitational pool is specified in the equation window. The corresponding graphical element is only a drawing. The user is reminded of this fact, by not connecting the “connections” all the way to the connectors. The user then knows that “something is fishy.”
