

## 8<sup>th</sup> Homework - Solution

- In this homework, we shall model and simulate a mechanical system as well as exercise the state selection algorithm.
- We shall first model a car bumping into a wall using the 1D mechanical (translational) wrapped bond graph library.
- We shall then model the same car using a bond graph directly.
- Subsequently, we shall read out the model equations from the bond graph.
- Finally, we shall change one of the state variables using the state selection algorithm.

## Mechanical System II

- Questions of interest:
  - Are the shock absorbers ( $k_2, B_2$ ) and the safety belts ( $k_1, B_1$ ) capable of preventing the driver from hitting his head on the front windshield if he drives with a velocity of **40 km/h** against a solid wall? What happens when the velocity at impact is **80 km/h**?
  - How large is the maximal force that the driver experiences at these velocities?
  - How large is the critical velocity, below which the driver neither hits his head on the windshield, nor breaks his ribs?

Mathematical Modeling of Physical Systems

## Mechanical System III

- Data:
  - Mass of vehicle ( $M$ ) = 1500 kg
  - Mass of driver ( $m$ ) = 100 kg
  - Stiffness of safety belt ( $k_1$ ) = 10'000 N/m
  - Stiffness of shock absorber ( $k_2$ ) = 300'000 N/m
  - Damping of safety belt ( $B_1$ ) = 500 Ns/m
  - Damping of shock absorber ( $B_2$ ) = 80'000 Ns/m
- Limit values:
  - Safety belt tested up to ( $F_1$ ) < 13'340 N
  - Ribs break beyond ( $F_2$ ) > 6670 N
  - Distance to windshield ( $d$ ) = 0.5 m

Mathematical Modeling of Physical Systems

## Mechanical System IV

- Model the car and the driver using two sliding masses of the translational sub-library of the mechanical sub-library of **BondLib**.
- Simulate the system across **0.5 sec** of simulated time, and answer the questions that were raised before.

## Mechanical System VI

The driver's head will hit the windshield.

The driver will break his ribs.

## Mechanical System VII

At the time of the impact with the windshield, the head of the driver has a velocity of  $7 \text{ m/s} = 25.2 \text{ km/h}$ .

Mathematical Modeling of Physical Systems

## Mechanical System VIII

The results are so depressing that a simulation with an initial velocity of  $80 \text{ km/h}$  is hardly necessary!

Mathematical Modeling of Physical Systems

## Mechanical System IX

- The system is linear. Hence we can compute the maximal velocity below which the head won't hit the windshield:

$$v_0 = 40 \cdot 0.5 / 0.81 = 24.7 \text{ km/h}$$

where  $0.81 \text{ m}$  is the largest distance in the simulation that we just carried out.

- Let us verify the results.

Mathematical Modeling of Physical Systems

## Mechanical System XI

- Draw a bond graph of this system.
- Simplify the bond graph using the diamond property.
- Add causality strokes.
- Simulate the simplified bond graph model using **BondLib**, and compare the results with those obtained earlier.

Mathematical Modeling of Physical Systems

## Mechanical System XII

The velocity of the car is entered as initial condition to the two inertias.

The bond graph can be simplified somewhat using the diamond property.

Mathematical Modeling of Physical Systems

## Mechanical System XV

- Read the model equations out of the simplified bond graph.
- What is the model order?
- Which are the natural state variables?
- We now wish to include the relative position and the relative velocity of the spring representing the seat belt among the set of desired state variables.
- Use the state selection algorithm to derive a modified set of equations that make use of the desired state variables.

## Mechanical System XVI

$$\frac{dv_M}{dt} = f_M/M$$

$$f_M = -(f_{k2} + f_{b2} + f_{kb})$$

$$\frac{df_{k2}}{dt} = v_M/k_2$$

$$f_{b2} = b_2 \cdot v_M$$

$$\frac{dv_m}{dt} = f_{kb}/m$$

$$v_{Mm} = v_M - v_m$$

$$f_{kb} = f_{k1} + f_{b1}$$

$$\frac{df_{k1}}{dt} = v_{Mm}/k_1$$

$$f_{b1} = b_1 \cdot v_{Mm}$$

$$\frac{dx_{Mm}}{dt} = v_{Mm}$$
