Executive Summary

Motivation: Hardware-software cooperative (cross-layer) techniques improve performance, quality of service, and security

Problem: Cross-layer techniques are challenging to implement and evaluate in real hardware because they require modifications across the stack

Our Goal is twofold:

- 1) Enable rapid implementation and evaluation of cross-layer techniques in real hardware
- 2) Quantify the overheads associated with a general metadata management system

Key Idea:

Develop a metadata management system (**MetaSys**) with hardware and software components that are reusable across cross-layer techniques to minimize programmer effort

Prototype: Xilinx Zedboard prototype using RISC-V Rocket Chip:

Low on-chip storage (0.2%) and memory storage (0.2%) overhead metadata management

Evaluation: Graph prefetching and memory protection case studies, extensive overhead characterization

- MetaSys-based graph prefetcher performs similar to state-of-the-art specialized prefetcher
- Low-overhead bounds-checking (14%) and return address protection (1.2%)
- Single general metadata management system scales well

Outline

- **Background**
 - **Cross-Layer Techniques**
 - **Evaluating Cross-Layer Techniques**
- MetaSys
 - Overview
 - Components
 - Operation
 - FPGA Prototype
- Case Studies
 - Prefetching
 - Memory Safety and Protection
- Characterizing a General Metadata Management System

Hardware Performance Optimizations

Today

Optimize for performance by **designing hardware** that infers and predicts program behavior

Cross-Layer Techniques

Future: Cross-Layer

Software can provide **information (metadata)** that the hardware is trying to infer

Example: Locality Descriptor (I)

Locality Descriptor [Vijaykumar+, ISCA'18a]

1. Express **data locality** (from software)
2. Exploit **data locality** (in hardware) in GPUs

The **programmer** or the **compiler**
describes key semantics
using a **software interface**

```
cudaMalloc(sm_mappings, size);
```

```
LocalityDescriptor ldesc(sm_mappings, size, INTER-THREAD, tile,
```

Data Structure

Metadata

Float

Char

Example: Locality Descriptor (II)

Hardware optimizations
leverage key program semantics
to improve performance significantly (e.g., >50%)

Benefits of Cross-Layer Techniques

- Performance optimizations
- Security enhancements
- Quality of service improvements
- Better programmability
- Better portability

Hardware

Software

Example prior work

[Vijaykumar+, ISCA'18a]

[Vijaykumar+, ISCA'18b]

[Koo+, ISCA'17]

[Yu+, CARVV'17]

[Mukkara+, ASPLOS'16]

[Ma+, ASPLOS'15]

...

Cross-Layer Evaluation Infrastructure

Evaluating cross-layer techniques is **non-trivial**

**Cycle-accurate
simulators**

FPGA prototypes

Need a **new infrastructure** to evaluate **a new cross-layer** technique

- Difficult given complexity (changes across the stack)

General Metadata Management System

A single general system can support multiple techniques

Key Benefit: Amortize the cost to implement each new technique

Outline

Cross-Layer Prefetching Techniques

Handle **challenging** access patterns

- Graph processing
- Pointer chasing
- Linear algebra
- ...

Example Prior Work

[Ainsworth+, ICS'16]

[Talati+, HPCA'21]

Case Study #1

New **cross-layer prefetching technique** for graph applications

- Leverage **graph data structure semantics**
 - Instead of relying on **program context** or **memory access history**

Graph Representation

Compressed sparse row (CSR) format

Traversing the Graph

Two types of indirection:

- 1 Using a single value
- 2 Using a range of values

Metadata required for prefetching:

- Type of indirection
- Base address of the next list
- Size of elements in both lists

Graph Prefetching Using MetaSys

Initialize metadata

- 1 Map metadata IDs to work, offset, and edges lists

- 2 **CREATE** metadata to express the characteristics
{type, base, base_next, size, size_next}
of each list

Prefetch

- 3 Load/store instruction triggers
metadata lookup in prefetcher

find what the application will access next using metadata

Example

base_properties +
(size_properties * 4)

Evaluation Methodology

CPU	25 MHz, in-order Rocket core
TLB	16 entry data TLB, LRU policy
L1 D&I\$	16 KiB, 4-way, 4 cycle, 64 B cache line, LRU, 2 MSHRs
DRAM	DDR3 1066 MT/s
Metadata Cache	NMRU policy, 128 entries, 38 bits/entry, 512 B granularity
Metadata Table	256 entries, 64 B entry

Workloads from the Ligra benchmark (graph applications):

- PageRank (PR), Shortest Path (SSSP), Collaborative Filtering (CF), Teenage Follower (TF), Triangle Counting (TC), Breadth-First Search (BFS), Radius Estimation (Radii), Connected Components (CC)

Evaluated configurations:

- Stride: Baseline system + a hardware stride prefetcher
- GraphPref: Specialized graph prefetcher
- MetaSys: Graph prefetching using MetaSys

Results

MetaSys improves performance by **11.2%** on average

Performs **similar to** the specialized prefetcher **GraphPref**
(within 0.2%)

 - Prefetching
 - **Memory Safety and Protection**
- Characterizing a General Metadata Management System

Memory Safety

Certain programming models are vulnerable to:

- **Buffer overflows** cause unintentional memory modifications

Memory-unsafe: When there is no **bounds checking** for pointers

```
char buffer[6];
```

```
string copy (buffer, "buffer overflow")
```

- Software bounds checking: Computationally **expensive**
- Hardware bounds checking: Too **specialized**

MetaSys allows **bounds checking** without additional hardware

Bounds Checking with MetaSys (I)

```
Array A = malloc (16 KB);  
MAP(Metadata ID M, Array A);  
for (i = 0 ; i < 17 KB ; i++)  
    CREATE(M);  
    STORE A[i], 1337;
```

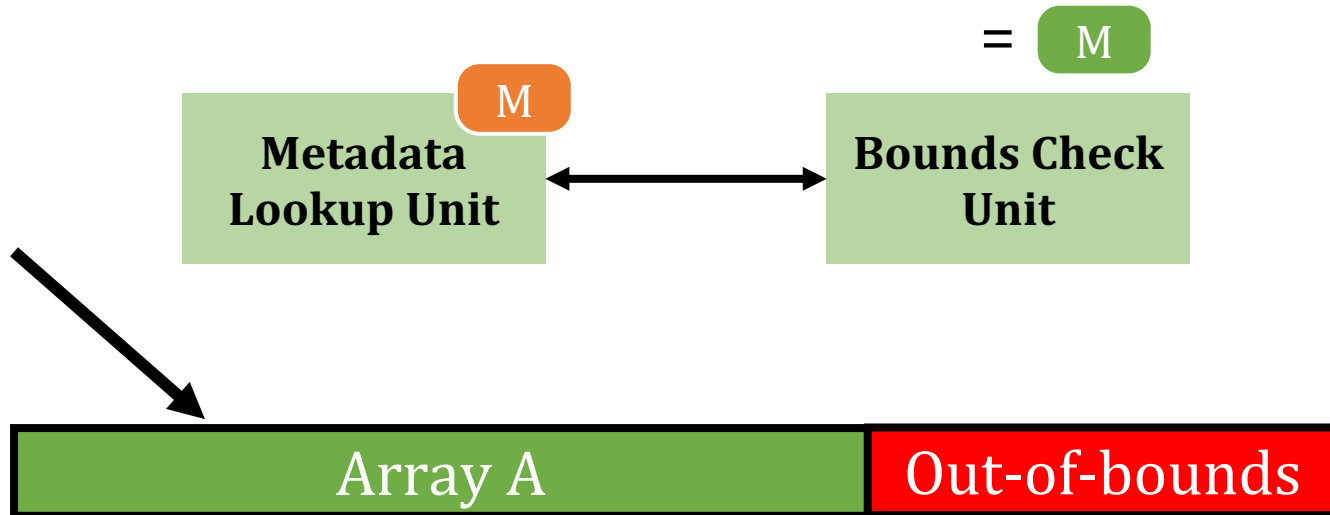

- 1 Allocate 16 KB of memory
Map Metadata ID M != 0 to Array A
- 2 Loop **exceeds** allocated memory range
Execute a CREATE instruction with ID = M before each STORE
- 3 Eventually, will cause buffer overflow

Bounds Checking with MetaSys (I)

```
Array A = malloc (16 KB);  
MAP(Metadata ID M, Array A);  
for (i = 0 ; i < 17 KB ; i++)  
    CREATE(M);  
    STORE A[i], 1337;
```

- 1 Allocate 16 KB of memory
Map Metadata ID M != 0 to Array A
- 2 Loop **exceeds** allocated memory range
Execute a CREATE instruction with ID = M before each STORE
- 3 Eventually, will cause buffer overflow

Bounds Checking with MetaSys (I)

```
Array A = malloc (16 KB);  
MAP(Metadata ID M, Array A);  
for (i = 0 ; i < 17 KB ; i++)  
    CREATE(M);  
    STORE A[i], 1337;
```

- 1 Allocate 16 KB of memory
Map Metadata ID M \neq 0 to Array A
- 2 Loop **exceeds** allocated memory range
Execute a CREATE instruction with ID = M before each STORE
- 3 Eventually, will cause buffer overflow

Bounds Checking with MetaSys (II)

Evaluation Methodology

- Mapping **granularity** of 64 B
 - Each 64 B non-contiguous memory location has an ID
- Evaluate Olden benchmarks
- Compare against a **software bounds checker**

- (I) MetaSys bounds checking incurs 14% performance overhead on average
- (II) Performs better than the software bounds checker

Return Address Protection with MetaSys

- **Characterizing a General Metadata Management System**

Characterizing MetaSys

Sources of system **overhead**:

1. Handling **dynamic metadata**
 - Communicating metadata SW → HW at runtime
2. Metadata **management** and **lookups**
 - Components retrieve metadata IDs
3. **Scaling** to multiple **components**
 - Multiple components access shared metadata support

Conduct **detailed** characterization study
to **understand** the overheads

Methodology

- Multiple workloads
 - Polybench, Ligra, and memory-intensive microbenchmarks
- Baseline MetaSys configuration (reminder)
 - 512 B mapping granularity
 - 128 entry metadata mapping cache
 - 256 entry metadata table
 - 64 B metadata
- Stress the metadata management system
 - Perform metadata lookups for every memory access

Overhead of Accessing Metadata

Average **real workload** lookup overhead is low: **2.7%**
(~0% min, ~14% max)

Low spatial & temporal locality workloads have high overheads
(**Random: 27%**)

Miss-only and all-access are similar in performance
(**0.05% difference**)

Effect of Mapping Granularity

Most workloads have **small performance overhead** even at the **smallest** mapping granularity

Some workloads experience **high overhead** even at the **largest** mapping granularity

Effect of Multiple Clients

Client 0: Lookup on **all memory accesses**

Client 1: Lookup on **all page table walk requests**

Average **real workload** overhead is 0.3%
(over one client)

Microbenchmarks experience higher overhead with more clients
In the paper: Investigate mechanisms to alleviate their overheads

MetaSys: A Practical Open-Source Metadata Management System to Implement and Evaluate Cross-Layer Optimizations

Nandita Vijaykumar, Ataberk Olgun, Konstantinos Kanellopoulos, Nisa Bostanci, Hasan Hassan, Mehrshad Lotfi, Phillip B. Gibbons, Onur Mutlu

This paper introduces the first open-source FPGA-based infrastructure, MetaSys, with a prototype in a RISC-V core, to enable the rapid implementation and evaluation of a wide range of cross-layer techniques in real hardware. Hardware-software cooperative techniques are powerful approaches to improve the performance, quality of service, and security of general-purpose processors. They are however typically challenging to rapidly implement and evaluate in real hardware as they require full-stack changes to the hardware, OS, system software, and instruction-set architecture (ISA). MetaSys implements a rich hardware-software interface and lightweight metadata support that can be used as a common basis to rapidly implement and evaluate new cross-layer techniques. We demonstrate MetaSys's versatility and ease-of-use by implementing and evaluating three cross-layer techniques for: (i) prefetching for graph analytics; (ii) bounds checking in memory unsafe languages, and (iii) return address protection in stack frames; each technique only requiring ~100 lines of Chisel code over MetaSys.

Using MetaSys, we perform the first detailed experimental study to quantify the performance overheads of using a single metadata management system to enable multiple cross-layer optimizations in CPUs. We identify the key sources of bottlenecks and system inefficiency of a general metadata management system. We design MetaSys to minimize these inefficiencies and provide increased versatility compared to previously-proposed metadata systems. Using three use cases and a detailed characterization, we demonstrate that a common metadata management system can be used to efficiently support diverse cross-layer techniques in CPUs.

OS Support

Support for:

- 1) managing MMT in physical address space
- 2) flushing PMTs on context switch
- 3) updating MMT tags and invalidating MMC on page swaps
- 4) trap into OS to perform checks (e.g., on bounds check failure)

Coherence/Consistency

- Private metadata tables of private components (e.g., L1 cache) are not coherent
- Private metadata tables of shared components are coherent automatically
 - Updates in PMTs due to CREATEs are visible to all threads immediately
 - Guaranteeing consistency requires use of barriers and fences
- Metadata mapping table shared across threads of the same process
 - Point of coherence is the mapping table, on a MAP, MMC entries in other cores are invalidated
 - Consistency still requires barriers and fences

Timing Sensitivity of Metadata

3 modes on how to handle a lookup:

- **Force stall:** Memory instruction that triggered a lookup cannot commit until the optimization is complete
 - Security use cases
- **No stall:** Metadata lookups never stall the core, but they are always resolved
 - E.g., in page placement, cache replacement
- **Best effort:** Lookups may be dropped before they complete
 - E.g., prefetcher training

Software Library

Table 2. The MetaSys software library function calls.

Library Function Call	Description
CREATE(<i>ClientID</i> , <i>TagID</i> , <i>*meta</i>)	<i>ClientID</i> -> PMT[<i>TagID</i>] = <i>*metadata</i>
MAP(<i>start*</i> , <i>end*</i> , <i>TagID</i>)	MMT[<i>start...end</i>] = <i>TagID</i>
UNMAP(<i>start*</i> , <i>end*</i>)	MMT[<i>start...end</i>] = 0

MetaSys vs XMem

Key difference:

- The whole system is open-sourced

Differences in interfaces:

Table 3. Comparison between MetaSys and XMem interfaces.

Operator	XMem [164]	MetaSys
CREATE	Compiler pragma to communicate static metadata at program load time.	Selects a hardware optimization, dynamically associates metadata with an ID, and communicates both to hardware at runtime (implemented as a new instruction).
(UN)MAP	Associate memory ranges with tag IDs (implemented as new instructions).	Same semantics and implementation as XMem.
(DE)ACTIVATE	Enable/disable optimizations associated with a tag ID (implemented as new instructions).	Does not exist as the same functionality can now be done with CREATE.

Existing Cross-Layer Infrastructure

PARD: Enable quality-of-service techniques

- Tag programs with an ID
- Propagate program ID with memory requests
- Hardware enforces QoS requirements on memory requests

Cheri: Fine-grained memory protection

- Capability registers replace address operands
- Tag capabilities with an ID
- Propagate capability IDs with memory requests
- Hardware enforces bounds checking, pointer integrity, etc.

MetaSys: Return Address Protection

- 1) Map return addresses to metadata id 1
- 2) Return address protection client performs metadata lookup on every store
- 3) If a store modifies a non-zero metadata

1.2% average performance overhead
(in contrast to software canary's 5.5%)

Additional Memory Accesses

Metadata Mapping Cache Hit Rate

Effect of Metadata Mapping Cache Size

Tagging Granularity vs TLB Misses

Effect of Address Translation

Alleviating Metadata Mapping Cache Contention

MAP/CREATE Instruction Overhead

This work introduces MetaSys:

- 1) A general metadata management system
- 2) Various hardware and software components in a **real prototype** to minimize developer effort
