SAFARI
Axiom

An Intelligent Architecture
Handles Data Well
How to Handle Data Well

- Ensure data does not overwhelm the components
  - via intelligent algorithms
  - via intelligent architectures
  - via whole system designs: algorithm-architecture-devices

- Take advantage of vast amounts of data and metadata
  - to improve architectural & system-level decisions

- Understand and exploit properties of (different) data
  - to improve algorithms & architectures in various metrics
Corollaries: Architectures Today …

- **Architectures are terrible at dealing with data**
  - Designed to mainly store and move data vs. to compute
  - They are processor-centric as opposed to data-centric

- **Architectures are terrible at taking advantage of vast amounts of data** (and metadata) available to them
  - Designed to make simple decisions, ignoring lots of data
  - They make human-driven decisions vs. data-driven

- **Architectures are terrible at knowing and exploiting different properties of application data**
  - Designed to treat all data as the same
  - They make component-aware decisions vs. data-aware
Fundamentally Better Architectures

Data-centric

Data-driven

Data-aware
We Need to Revisit the Entire Stack

We can get there step by step
To achieve the highest **energy efficiency** and **performance**:

**we must take an expanded view**

of computer architecture

Data-Centric (Memory-Centric) Architectures
Data-Centric Architectures: Properties

- **Process data where it resides** *(where it makes sense)*
  - Processing in and near memory structures

- **Low-latency and low-energy data access**
  - Low latency memory
  - Low energy memory

- **Low-cost data storage and processing**
  - High capacity memory at low cost: hybrid memory, compression

- **Intelligent data management**
  - Intelligent controllers handling robustness, security, cost, perf.
Processing Data
Where It Makes Sense
Processing in/near Memory: An Old Idea

IEEE TRANSACTIONS ON COMPUTERS, VOL. C-18, NO. 8, AUGUST 1969

Cellular Logic-in-Memory Arrays

WILLIAM H. KAUTZ, MEMBER, IEEE

Abstract—As a direct consequence of large-scale integration, many advantages in the design, fabrication, testing, and use of digital circuitry can be achieved if the circuits can be arranged in a two-dimensional iterative, or cellular, array of identical elementary networks, or cells. When a small amount of storage is included in each cell, the same array may be regarded either as a logically enhanced memory array, or as a logic array whose elementary gates and connections can be “programmed” to realize a desired logical behavior.

In this paper the specific engineering features of such cellular logic-in-memory (CLIM) arrays are discussed, and one such special-purpose array, a cellular sorting array, is described in detail to illustrate how these features may be achieved in a particular design. It is shown how the cellular sorting array can be employed as a single-address, multiword memory that keeps in order all words stored within it. It can also be used as a content-addressed memory, a pushdown memory, a buffer memory, and (with a lower logical efficiency) a programmable array for the realization of arbitrary switching functions. A second version of a sorting array, operating on a different sorting principle, is also described.

Index Terms—Cellular logic, large-scale integration, logic arrays logic in memory, push-down memory, sorting, switching functions.

Fig. 1. Cellular sorting array I.

Processing in/near Memory: An Old Idea

A Logic-in-Memory Computer

HAROLD S. STONE

Abstract—If, as presently projected, the cost of microelectronic arrays in the future will tend to reflect the number of pins on the array rather than the number of gates, the logic-in-memory array is an extremely attractive computer component. Such an array is essentially a microelectronic memory with some combinational logic associated with each storage element.
Why In-Memory Computation Today?

- **Push from Technology**
  - Memory technology scaling is not keeping up
  - Lots of scaling issues demand intelligence in memory

- **Pull from Applications & Systems**
  - Data access is the major bottleneck
  - Systems are energy & power limited
  - Data movement much more energy-hungry than computation
  - Need all at the same time: performance, energy, sustainability
  - We can improve all metrics by minimizing data movement

- **Designs are squeezed in the middle**
Why In-Memory Computation Today?

- **Push from Technology**
  - DRAM Scaling at jeopardy
    - Controllers close to DRAM
    - Industry open to new memory architectures
Why In-Memory Computation Today?

And, many other experimental chips and startups

Intelligent Memory Controllers Can Avoid Many Failures & Enable Better Scaling
The Push from Circuits and Devices

Main Memory Needs

Intelligent Controllers
Why In-Memory Computation Today?

- **Push from Technology**
  - DRAM Scaling at jeopardy
    → Controllers close to DRAM
    → Industry open to new memory architectures

- **Pull from Systems and Applications**
  - Data access is the major system and application bottleneck
  - Systems are energy & power limited
  - Data movement much more energy-hungry than computation
Three Key Systems & Application Trends

1. Data access is the major bottleneck
   - Applications are increasingly data hungry

2. Energy consumption is a key limiter

3. Data movement energy dominates compute
   - Especially true for off-chip to on-chip movement
Do We Want This?

Source: V. Milutinovic
Or This?

Source: V. Milutinovic
Challenge and Opportunity for Future

High Performance, Energy Efficient, Sustainable
(All at the Same Time)
The Problem

Data access is the major performance and energy bottleneck

Our current design principles cause great energy waste
(and great performance loss)
The Problem

Processing of data is performed far away from the data.
A Computing System

- Three key components
- Computation
- Communication
- Storage/memory

Burks, Goldstein, von Neumann, “Preliminary discussion of the logical design of an electronic computing instrument,” 1946.

A Computing System

- Three key components
- Computation
- Communication
- Storage/memory

Burks, Goldstein, von Neumann, “Preliminary discussion of the logical design of an electronic computing instrument,” 1946.

Today’s Computing Systems

- Are overwhelmingly processor centric
- All data processed in the processor → at great system cost
- Processor is heavily optimized and is considered the master
- Data storage units are dumb and are largely unoptimized
Yet ...

- "It’s the Memory, Stupid!" (Richard Sites, MPR, 1996)

I expect that over the coming decade memory subsystem design will be the only important design issue for microprocessors.

The Performance Perspective

- Onur Mutlu, Jared Stark, Chris Wilkerson, and Yale N. Patt, "Runahead Execution: An Alternative to Very Large Instruction Windows for Out-of-order Processors"

One of the 15 computer arch. papers of 2003 selected as Top Picks by IEEE Micro. HPCA Test of Time Award (awarded in 2021).

Runahead Execution: An Alternative to Very Large Instruction Windows for Out-of-order Processors

The Performance Perspective (Today)

- All of Google’s Data Center Workloads (2015):

Figure 11: Half of cycles are spent stalled on caches.

Perils of Processor-Centric Design

- **Grossly-imbalanced systems**
  - Processing done only in **one place**
  - All else just stores and moves data: **data moves a lot**
    - Energy inefficient
    - Low performance
    - Complex

- **Overly complex and bloated processor (and accelerators)**
  - To tolerate data access from memory
  - Complex hierarchies and mechanisms
    - Energy inefficient
    - Low performance
    - Complex
Most of the system is dedicated to storing and moving data.

Yet, system is still bottlenecked by memory.
Communication Dominates Arithmetic

- 64-bit DP: 20pJ
- 256-bit buses
- 256-bit access: 8 KB SRAM
- DRAM Rd/Wr: 16 nJ
- Efficient off-chip link: 500 pJ
- 1 nJ
- 50 pJ
- 26 pJ
- 256 pJ
- 20 mm

Dally, HiPEAC 2015
A memory access consumes ~100-1000X the energy of a complex addition.
Data Movement vs. Computation Energy

Energy for a 32-bit Operation (log scale)

- Energy (pJ)
- ADD (int) Relative Cost

ADD (int) | ADD (float) | Register File | MULT (int) | MULT (float) | SRAM | DRAM
---|---|---|---|---|---|---
0.1 | 0.9 | 1 | 3.1 | 3.7 | 5 | 640

A memory access consumes 6400X the energy of a simple integer addition.
Data Movement vs. Computation Energy

- **Data movement** is a major system energy bottleneck
  - Comprises **41%** of mobile system energy during web browsing [2]
  - Costs ~**115** times as much energy as an ADD operation [1, 2]

Abstract

Modern computing systems are overwhelmingly designed to move data to computation. This design choice goes directly against at least three key trends in computing that cause performance, scalability and energy bottlenecks: (1) data access is a key bottleneck as many important applications are increasingly data-intensive, and memory bandwidth and energy do not scale well, (2) energy consumption is a key limiter in almost all computing platforms, especially server and mobile systems, (3) data movement, especially off-chip to on-chip, is very expensive in terms of bandwidth, energy and latency, much more so than computation. These trends are especially severely-felt in the data-intensive server and energy-constrained mobile systems of today.

At the same time, conventional memory technology is facing many technology scaling challenges in terms of reliability, energy, and performance. As a result, memory system architects are open to organizing memory in different ways and making it more intelligent, at the expense of higher cost. The emergence of 3D-stacked memory plus logic, the adoption of error correcting codes inside the latest DRAM chips, proliferation of different main memory standards and chips, specialized for different purposes (e.g., graphics, low-power, high bandwidth, low latency), and the necessity of designing new solutions to serious reliability and security issues, such as the RowHammer phenomenon, are evidence of this trend.

This chapter discusses recent research that aims to practically enable computation close to data; an approach we call processing-in-memory (PIM). PIM places computation mechanisms in or near where the data is stored (i.e., inside the memory chips, in the logic layer of 3D-stacked memory, or in the memory controllers), so that data movement between the computation units and memory is reduced or eliminated. While the general idea of PIM is not new, we discuss motivating trends in applications as well as memory circuits/technology that greatly exacerbate the need for enabling it in modern computing systems. We examine at least two promising new approaches to designing PIM systems to accelerate important data-intensive applications: (1) processing using memory by exploiting analog operational properties of DRAM chips to perform massively-parallel operations in memory, with low-cost changes, (2) processing near memory by exploiting 3D-stacked memory technology design to provide high memory bandwidth and low memory latency to in-memory logic. In both approaches, we describe and tackle relevant cross-layer research, design, and adoption challenges in devices, architecture, systems, and programming models. Our focus is on the development of in-memory processing designs that can be adopted in real computing platforms at low cost. We conclude by discussing work on solving key challenges to the practical adoption of PIM.

Keywords: memory systems, data movement, main memory, processing-in-memory, near-data processing, computation-in-memory, processing using memory, processing near memory, 3D-stacked memory, non-volatile memory, energy efficiency, high-performance computing, computer architecture, computing paradigm, emerging technologies, memory scaling, technology scaling, dependable systems, robust systems, hardware security, system security, latency, low-latency computing
1. Introduction

Main memory, built using the Dynamic Random Access Memory (DRAM) technology, is a major component in nearly all computing systems, including servers, cloud platforms, mobile/embedded devices, and sensor systems. Across all of these systems, the data working set sizes of modern applications are rapidly growing, while the need for fast analysis of such data is increasing. Thus, main memory is becoming an increasingly significant bottleneck across a wide variety of computing systems and applications [1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16]. Alleviating the main memory bottleneck requires the memory capacity, energy, cost, and performance to all scale in an efficient manner across technology generations. Unfortunately, it has become increasingly difficult in recent years, especially the past decade, to scale all of these dimensions [1, 2, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49], and thus the main memory bottleneck has been worsening.

A major reason for the main memory bottleneck is the high energy and latency cost associated with data movement. In modern computers, to perform any operation on data that resides in main memory, the processor must retrieve the data from main memory. This requires the memory controller to issue commands to a DRAM module across a relatively slow and power-hungry off-chip bus (known as the memory channel). The DRAM module sends the requested data across the memory channel, after which the data is placed in the caches and registers. The CPU can perform computation on the data once the data is in its registers. Data movement from the DRAM to the CPU incurs long latency and consumes a significant amount of energy [7, 50, 51, 52, 53, 54]. These costs are often exacerbated by the fact that much of the data brought into the caches is not reused by the CPU [52, 53, 55, 56], providing little benefit in return for the high latency and energy cost.

The cost of data movement is a fundamental issue with the processor-centric nature of contemporary computer systems. The CPU is considered to be the master in the system, and computation is performed only in the processor (and accelerators). In contrast, data storage and communication units, including the main memory, are treated as unintelligent workers that are incapable of computation. As a result of this processor-centric design paradigm, data moves a lot in the system between the computation units and communication/ storage units so that computation can be done on it. With the increasingly data-centric nature of contemporary and emerging appli-
We Need to Think Differently from the Past Approaches
Processing in Memory: Two Approaches

1. Processing using Memory
2. Processing near Memory
5.2. **Two Approaches: Processing Using Memory (PUM) vs. Processing Near Memory (PNM)**

Many recent works take advantage of the memory technology innovations that we discuss in Section 5.1 to enable and implement PIM. We find that these works generally take one of two approaches, which are categorized in Table 1: (1) **processing using memory** or (2) **processing near memory**. We briefly describe each approach here. Sections 6 and 7 will provide example approaches and more detail for both.

### Table 1: Summary of enabling technologies for the two approaches to PIM used by recent works. Adapted from [309].

PACT 2021
Executive Summary

Context: We extensively analyze a state-of-the-art edge ML accelerator (Google Edge TPU) using 24 Google edge models
- Wide range of models (CNNs, LSTMs, Transducers, RCNNs)

Problem: The Edge TPU accelerator suffers from three challenges:
- It operates significantly below its peak throughput
- It operates significantly below its theoretical energy efficiency
- It inefficiently handles memory accesses

Key Insight: These shortcomings arise from the monolithic design of the Edge TPU accelerator
- The Edge TPU accelerator design does not account for layer heterogeneity

Key Mechanism: A new framework called Mensa
- Mensa consists of heterogeneous accelerators whose dataflow and hardware are specialized for specific families of layers

Key Results: We design a version of Mensa for Google edge ML models
- Mensa improves performance and energy by $3.0X$ and $3.1X$
- Mensa reduces cost and improves area efficiency
We analyze inference execution using 24 edge NN models.
Diversity Across the Models

Insight 1: there is **significant variation** in terms of layer characteristics **across the models**

- Layers from CNNs and RCNNs
- Layers from LSTMs and Transducers

![Graph showing diversity across models with FLOP/Byte vs. Parameter Footprint (MB)]
Diversity Within the Models

**Insight 2:** even within each model, layers exhibit significant variation in terms of layer characteristics.

For example, our analysis of edge CNN models shows:

**Variation in MAC intensity:** up to 200x across layers

**Variation in FLOP/Byte:** up to 244x across layers
Key observation: the majority of layers group into a small number of layer families

Families 1 & 2: low parameter footprint, high data reuse and MAC intensity → compute-centric layers

Families 3, 4 & 5: high parameter footprint, low data reuse and MAC intensity → data-centric layers
Mensa-G reduces energy consumption by 3.0X compared to the baseline Edge TPU

SAFARI
Mensa-G improves inference throughput by 3.1x compared to the baseline Edge TPU.

[Preliminary arXiv version]

Processing in Memory: Two Approaches

1. Processing using Memory
2. Processing near Memory
5.2. Two Approaches: Processing Using Memory (PUM) vs. Processing Near Memory (PNM)

Many recent works take advantage of the memory technology innovations that we discuss in Section 5.1 to enable and implement PIM. We find that these works generally take one of two approaches, which are categorized in Table 1: (1) processing using memory or (2) processing near memory. We briefly describe each approach here. Sections 6 and 7 will provide example approaches and more detail for both.

Table 1: Summary of enabling technologies for the two approaches to PIM used by recent works. Adapted from [309].

<table>

| Processing Near Memory | Logic layers in 3D-stacked memory  
Silicon interposers  
Logic in memory controllers |

Processing using memory (PUM) exploits the existing memory architecture and the operational principles of the memory circuitry to enable operations within main memory with minimal changes. PUM makes use

Approach 1: Processing Using Memory

- Take advantage of operational principles of memory to perform bulk data movement and computation in memory
  - Can exploit internal connectivity to move data
  - Can exploit analog computation capability
  - ...

Examples: RowClone, In-DRAM AND/OR, Gather/Scatter DRAM

- RowClone: Fast and Efficient In-DRAM Copy and Initialization of Bulk Data (Seshadri et al., MICRO 2013)
- Fast Bulk Bitwise AND and OR in DRAM (Seshadri et al., IEEE CAL 2015)
- Gather-Scatter DRAM: In-DRAM Address Translation to Improve the Spatial Locality of Non-unit Strided Accesses (Seshadri et al., MICRO 2015)
- "Ambit: In-Memory Accelerator for Bulk Bitwise Operations Using Commodity DRAM Technology" (Seshadri et al., MICRO 2017)
Starting Simple: Data Copy and Initialization

*memmove & memcpy: 5% cycles in Google’s datacenter [Kanev+ ISCA’15]*

- Forking
- Zero initialization (e.g., security)
- Checkpointing
- VM Cloning
- Deduplication
- Page Migration
- Many more

**SAFARI**
Future Systems: In-Memory Copy

1. Low latency
2. Low bandwidth utilization
3. No cache pollution
4. No unwanted data movement

1046ns, 3.6uJ → 90ns, 0.04uJ
RowClone: In-DRAM Row Copy

Idea: Two consecutive ACTivates
Negligible HW cost

Real Processing Using Memory Prototype

https://github.com/cmu-safari/pidram
Real Processing Using Memory Prototype

Building a PiDRAM Prototype

To build PiDRAM's prototype on Xilinx ZC706 boards, developers need to use the two sub-projects in this directory. `fpga-zynq` is a repository branched off of UCBA-BAR's `fpga-zynq` repository. We use `fpga-zynq` to generate rocket chip designs that support end-to-end DRAM PuM execution. `controller-hardware` is where we keep the main Vivado project and Verilog sources for PiDRAM's memory controller and the top level system design.

Rebuilding Steps

1. Navigate into `fpga-zynq` and read the README file to understand the overall workflow of the repository
   - Follow the readme in `fpga-zynq/rocket-chip/riscv-tools` to install dependencies
2. Create the Verilog source of the rocket chip design using the `ZynqCopyFPGACfg`
   - Navigate into zc706, then run `make rocket CONFIG=ZynqCopyFPGACfg -j number of cores`
3. Copy the generated Verilog file (should be under zc706/src) and overwrite the same file in `controller-hardware/source/hdl/impl/rocket-chip`
4. Open the Vivado project in `controller-hardware/Vivado_Project` using Vivado 2016.2
5. Generate a bitstream
6. Copy the bitstream (`system_top.bit`) to `fpga-zynq/zc706`
7. Use the `./build_script.sh` to generate the new `boot.bin` under `fpga-images-zc706`, you can use this file to program the FPGA using the SD-Card
   - For details, follow the relevant instructions in `fpga-zynq/README.md`

You can run programs compiled with the RISC-V Toolchain supplied within the `fpga-zynq` repository. To install the toolchain, follow the instructions under `fpga-zynq/rocket-chip/riscv-tools`.

Generating DDR3 Controller IP sources

We cannot provide the sources for the Xilinx PHY IP we use in PiDRAM's memory controller due to licensing issues. We describe here how to regenerate them using Vivado 2016.2. First, you need to generate the IP RTL files:

1- Open IP Catalog
2- Find "Memory Interface Generator (MIG 7 Series)" IP and double click

Lecture on RowClone & Processing using DRAM

Mindset: Memory as an Accelerator

Memory similar to a “conventional” accelerator

https://www.youtube.com/watch?v=n6Pwg1qax_E&list=PL5Q2soXY2Zi_7UBNmC9B8Yr5JSwTG9yH4&index=4
Mindset: Memory as an Accelerator

Memory similar to a “conventional” accelerator
(Truly) In-Memory Computation

- We can support in-DRAM AND, OR, NOT, MAJ
- At low cost
- Using analog computation capability of DRAM
  - Idea: activating multiple rows performs computation
- 30-60X performance and energy improvement

- New memory technologies enable even more opportunities
  - Memristors, resistive RAM, phase change mem, STT-MRAM, ...
  - Can operate on data with minimal movement
In-DRAM AND/OR: Triple Row Activation

Final State
\[ AB + BC + AC \]

\[ C(A + B) + \sim C(AB) \]

Bulk Bitwise Operations in Workloads

- Bitmap indices (database indexing)
- Set operations
- Encryption algorithms
- BitWeaving (database queries)
- BitFunnel (web search)
- DNA sequence mapping

SIMDRAM Key Results

Evaluated on:
- 16 complex in-DRAM operations
- 7 commonly-used real-world applications

SIMDRAM provides:

• $88 \times$ and $5.8 \times$ the **throughput** of a CPU and a high-end GPU, respectively, over 16 operations

• $257 \times$ and $31 \times$ the **energy efficiency** of a CPU and a high-end GPU, respectively, over 16 operations

• $21 \times$ and $2.1 \times$ the **performance** of a CPU and a high-end GPU, over seven real-world applications

Eliminating the Adoption Barriers

Processing-in-Memory in the Real World
This does not include many experimental chips and startups
UPMEM Processing-in-DRAM Engine (2019)

- Processing in DRAM Engine
- Includes **standard DIMM modules**, with a **large number of DPU processors** combined with DRAM chips.

- Replaces **standard** DIMMs
  - DDR4 R-DIMM modules
    - 8GB+128 DPUs (16 PIM chips)
    - Standard 2x-nm DRAM process
  - **Large amounts of** compute & memory bandwidth

---

UPMEM Memory Modules

- E19: 8 chips DIMM (1 rank). DPUs @ 267 MHz
- P21: 16 chips DIMM (2 ranks). DPUs @ 350 MHz

Benchmarking a New Paradigm: An Experimental Analysis of a Real Processing-in-Memory Architecture

JUAN GÓMEZ-LUNA, ETH Zürich, Switzerland

Many modern workloads, such as neural networks, databases, and graph processing, are fundamentally memory-bound. For such workloads, the data movement between main memory and CPU cores imposes a significant overhead in terms of both latency and energy. A major reason is that this communication happens through a narrow bus with high latency and limited bandwidth, and the low data reuse in memory-bound workloads is insufficient to amortize the cost of main memory access. Fundamentally unbalancing this data movement bottleneck requires a paradigm where the memory system assumes an active role in computing by integrating processing capabilities. This paradigm is known as processing-in-memory (PIM).

Recent research explores different forms of PIM architecture, motivated by the emergence of new 3D-stacked memory technologies that integrate memory with a logic layer where processing elements can be easily placed. Past works evaluate these architectures in simulation or, at best, with simplified hardware prototypes. In contrast, the UPNEM company has designed and manufactured the first publicly available real-world PIM architecture. The UPNEM PIM architecture combines traditional DRAM memory arrays with general-purpose in-order cores, called DPU Processing Units (DPU), integrated in the same chip.

This paper provides the first comprehensive analysis of the first publicly available real-world PIM architecture. We make two key contributions. First, we conduct an experimental characterization of the UPNEM board and PIM system using microbenchmarks to assess various architecture limits such as compute throughput and memory bandwidth, yielding new insights. Second, we present PIM (dual-core) memory benchmarks, a benchmark suite of 6 workloads from different application domains (e.g., dense/sparse linear algebra, databases, data analytics, graph processing, neural networks, bioinformatics, image processing), which we identify as memory-bound. We evaluate the performance and scaling characteristics of PIM benchmarks on the UPNEM PIM architecture, and compare their performance and energy consumption to their state-of-the-art CPU and GPU counterparts. Our extensive evaluation conducted on two real UPNEM-based PIM systems with 440 and 2,560 DPUs provides new insights about suitability of different workloads to the PIM system, programming recommendations for software designers, and suggestions and hints for hardware and architecture designers of future PIM systems.

PrIM (Processing-In-Memory Benchmarks)

PrIM is the first benchmark suite for a real-world processing-in-memory (PIM) architecture. PrIM is developed to evaluate, analyze, and characterize the first publicly-available real-world processing-in-memory (PIM) architecture, the UPMEM PIM architecture. The UPMEM PIM architecture combines traditional DRAM memory arrays with general-purpose in-order cores, called DRAM Processing Units (DPUs), integrated in the same chip.

PrIM provides a common set of workloads to evaluate the UPMEM PIM architecture with and can be useful for programming, architecture and system researchers all alike to improve multiple aspects of future PIM hardware and software. The workloads have different characteristics, exhibiting heterogeneity in their memory access patterns, operations and data types, and communication patterns. This repository also contains baseline CPU and GPU implementations of PrIM benchmarks for comparison purposes.

PrIM also includes a set of microbenchmarks can be used to assess various architecture limits such as compute throughput and memory bandwidth.

Inter-DPU Communication

- There is **no direct communication channel between DPUs**

Inter-DPU communication takes places via the host CPU using CPU-DPU and DPU-CPU transfers.

Example communication patterns:
- Merging of partial results to obtain the final result
- Only DPU-CPU transfers
- Redistribution of intermediate results for further computation
- DPU-CPU transfers and CPU-DPU transfers

ONUR MUTLU, ETH Zürich, Switzerland

Data movement between the CPU and main memory is a first-order obstacle against improving performance, scalability, and energy efficiency in modern systems. Computer systems employ a range of techniques to reduce overheads tied to data movement, spanning from traditional mechanisms (e.g., deep multi-level cache hierarchies, aggressive hardware prefetchers) to emerging techniques such as Near-Data Processing (NDP), where some computation is moved close to memory. Prior NDP works investigate the root causes of data movement bottlenecks using different profiling methodologies and tools. However, there is still a lack of understanding about the key metrics that can identify different data movement bottlenecks and their relation to traditional and emerging data movement mitigation mechanisms. Our goal is to methodically identify potential sources of data movement over a broad set of applications and to comprehensively compare traditional compute-centric data movement mitigation techniques (e.g., caching and prefetching) to more memory-centric techniques (e.g., NDP), thereby developing a rigorous understanding of the best techniques to mitigate each source of data movement.

With this goal in mind, we perform the first large-scale characterization of a wide variety of applications, across a wide range of application domains, to identify fundamental program properties that lead to data movement to/from main memory. We develop the first systematic methodology to classify applications based on the sources contributing to data movement bottlenecks. From our large-scale characterization of 77K functions across 345 applications, we select 144 functions to form the first open-source benchmark suite (DAMOV) for main memory data movement studies. We select a diverse range of functions that (1) represent different types of data movement bottlenecks, and (2) come from a wide range of application domains. Using NDP as a case study, we identify new insights about the different data movement bottlenecks and use these insights to determine the most suitable data movement mitigation mechanism for a particular application. We open-source DAMOV and the complete source code for our new characterization methodology at https://github.com/CMU-SAFARI/DAMOV.
When to Employ Near-Data Processing?

Mobile consumer workloads

Samsung Develops Industry’s First High Bandwidth Memory with AI Processing Power

Samsung Electronics, the world leader in advanced memory technology, today announced that it has developed the industry’s first High Bandwidth Memory (HBM) integrated with artificial intelligence (AI) processing power — the HBM-PIM. The new processing-in-memory (PIM) architecture brings powerful AI computing capabilities inside high-performance memory, to accelerate large-scale processing in data centers, high performance computing (HPC) systems and AI-enabled mobile applications.

Kwangil Park, senior vice president of Memory Product Planning at Samsung Electronics stated, “Our groundbreaking HBM-PIM is the industry’s first programmable PIM solution tailored for diverse AI-driven workloads such as HPC, training and inference. We plan to build upon this breakthrough by further collaborating with AI solution providers for even more advanced PIM-powered applications.”

FIMDRAM based on HBM2

Chip Specification

- 128DQ / 8CH / 16 banks / BL4
- 32 PCU blocks (1 FIM block/2 banks)
- 1.2 TFLOPS (4H)
- FP16 ADD / Multiply (MUL) / Multiply-Accumulate (MAC) / Multiply-and-Add (MAD)
Programmable Computing Unit

- Configuration of PCU block
  - Interface unit to control data flow
  - Execution unit to perform operations
  - Register group
    - 32 entries of CRF for instruction memory
    - 16 GRF for weight and accumulation
    - 16 SRF to store constants for MAC operations

SK hynix Develops PIM, Next-Generation AI Accelerator

February 16, 2022

Seoul, February 16, 2022

SK hynix (or “the Company”, www.skhynix.com) announced on February 16 that it has developed PIM	r, a next-
generation memory chip with computing capabilities.

*PIM* (Processing In Memory): A next-generation technology that provides a solution for data congestion issues for AI and big data by adding computational functions to semiconductor memory.

It has been generally accepted that memory chips store data and CPU or GPU, like human brain, process data. SK hynix, following its challenge to such notion and efforts to pursue innovation in the next-generation smart memory, has found a breakthrough solution with the development of the latest technology.

SK hynix plans to showcase its PIM development at the world’s most prestigious semiconductor conference, 2022 ISSCC*, in San Francisco at the end of this month. The company expects continued efforts for innovation of this technology to bring the memory-centric computing, in which semiconductor memory plays a central role, a step closer to the reality in devices such as smartphones.

*ISSCC: The International Solid-State Circuits Conference will be held virtually from Feb. 20 to Feb. 24 this year with a theme of “Intelligent Silicon for a Sustainable World”*

For the first product that adopts the PIM technology, SK hynix has developed a sample of GDDR6-AiM (Accelerator” in memory). The GDDR6-AiM adds computational functions to GDDR6’ memory chips, which process data at 16Gb/s. A combination of GDDR6-AiM with CPU or GPU instead of a typical DRAM makes certain computation speed 16 times faster. GDDR6-AiM is widely expected to be adopted for machine learning, high-performance computing, and big data computation and storage.

Concluding Remarks
Concluding Remarks

- We must design systems to be balanced, high-performance, energy-efficient (all at the same time) → intelligent systems
  - Data-centric, data-driven, data-aware

- Enable computation capability inside and close to memory
  - This can
    - Lead to orders-of-magnitude improvements
    - Enable new applications & computing platforms
    - Enable better understanding of nature
    - ...

- Future of truly memory-centric computing is bright
  - We need to do research & design across the computing stack
Fundamentally Better Architectures

Data-centric

Data-driven

Data-aware
We Need to Revisit the Entire Stack

We can get there step by step
We Need to Exploit Good Principles

- Data-centric system design
- All components intelligent
- Better (cross-layer) communication, better interfaces
- Better-than-worst-case design
- Heterogeneity
- Flexibility, adaptability

Open minds
A Blueprint for Fundamentally Better Architectures

Error Characterization, Mitigation, and Recovery in Flash-Memory-Based Solid-State Drives

This paper reviews the most recent advances in solid-state drive (SSD) error characterization, mitigation, and data recovery techniques to improve both SSD’s reliability and lifetime.

System Desirables

- Self-managing, independent components
- All components intelligent & equal partners
- Easy collaboration & partitioning across all components
- Fine-grained communication of data & tasks
- Seamless caching & translation & protection anywhere
- Execution anywhere without rewriting code
- Flexibility, adaptability, self-optimization

Data-Driven Architectures
Corollaries: Architectures Today …

- Architectures are terrible at dealing with data
  - Designed to mainly store and move data vs. to compute
  - They are processor-centric as opposed to data-centric

- Architectures are terrible at taking advantage of vast amounts of data (and metadata) available to them
  - Designed to make simple decisions, ignoring lots of data
  - They make human-driven decisions vs. data-driven decisions

- Architectures are terrible at knowing and exploiting different properties of application data
  - Designed to treat all data as the same
  - They make component-aware decisions vs. data-aware
Exploiting Data to Design Intelligent Architectures
System Architecture Design Today

- Human-driven
  - Humans design the policies (how to do things)

- Many (too) simple, short-sighted policies all over the system

- No automatic data-driven policy learning

- (Almost) no learning: cannot take lessons from past actions

Can we design fundamentally intelligent architectures?
An Intelligent Architecture

- Data-driven
  - Machine learns the “best” policies (how to do things)

- Sophisticated, workload-driven, changing, far-sighted policies

- Automatic data-driven policy learning

- All controllers are intelligent data-driven agents

How do we start?
Self-Optimizing Memory Controllers
Memory Controller

Resolves memory contention by scheduling requests

How to schedule requests to maximize system performance?
Why are Memory Controllers Difficult to Design?

- Need to obey **DRAM timing constraints** for correctness
  - There are many (50+) timing constraints in DRAM
  - twTR: Minimum number of cycles to wait before issuing a read command after a write command is issued
  - tRC: Minimum number of cycles between the issuing of two consecutive activate commands to the same bank
  - ...

- Need to **keep track of many resources** to prevent conflicts
  - Channels, banks, ranks, data bus, address bus, row buffers, ...

- Need to handle **DRAM refresh**

- Need to **manage power** consumption

- Need to **optimize performance & QoS** (in the presence of constraints)
  - Reordering is not simple
  - Fairness and QoS needs complicates the scheduling problem

- ...

(tRAS+tRP)
Memory Controller Design Is Becoming More Difficult

- Heterogeneous agents: CPUs, GPUs, and HWAs
- Main memory interference between CPUs, GPUs, HWAs
- Many timing constraints for various memory types
- Many goals at the same time: performance, fairness, QoS, energy efficiency, ...
Reality and Dream

- **Reality**: It difficult to design a policy that maximizes performance, QoS, energy-efficiency, ...
  - Too many things to think about
  - Continuously changing workload and system behavior

- **Dream**: Wouldn’t it be nice if the DRAM controller automatically found a good scheduling policy on its own?
Self-Optimizing DRAM Controllers

- Problem: DRAM controllers are difficult to design
  - It is difficult for human designers to design a policy that can adapt itself very well to different workloads and different system conditions

- Idea: A memory controller that adapts its scheduling policy to workload behavior and system conditions using machine learning.

- Observation: Reinforcement learning maps nicely to memory control.

- Design: Memory controller is a reinforcement learning agent
  - It dynamically and continuously learns and employs the best scheduling policy to maximize long-term performance.
Self-Optimizing DRAM Controllers

Goal: Learn to choose actions to maximize $r_0 + \gamma r_1 + \gamma^2 r_2 + \ldots$ ($0 \leq \gamma < 1$)

Figure 2: (a) Intelligent agent based on reinforcement learning principles;
Self-Optimizing DRAM Controllers

- Dynamically adapt the memory scheduling policy via interaction with the system at runtime
  - Associate system states and actions (commands) with long term reward values: each action at a given state leads to a learned reward
  - Schedule command with highest estimated long-term reward value in each state
  - Continuously update reward values for <state, action> pairs based on feedback from system

Figure 4: High-level overview of an RL-based scheduler.
States, Actions, Rewards

- **Reward function**
  - +1 for scheduling Read and Write commands
  - 0 at all other times

Goal is to maximize long-term data bus utilization

- **State attributes**
  - Number of reads, writes, and load misses in transaction queue
  - Number of pending writes and ROB heads waiting for referenced row
  - Request’s relative ROB order

- **Actions**
  - Activate
  - Write
  - Read - load miss
  - Read - store miss
  - Precharge - pending
  - Precharge - preemptive
  - NOP
Performance Results

Large, robust performance improvements over many human-designed policies

Figure 7: Performance comparison of in-order, FR-FCFS, RL-based, and optimistic memory controllers

Figure 15: Performance comparison of FR-FCFS and RL-based memory controllers on systems with 6.4GB/s and 12.8GB/s peak DRAM bandwidth
Self Optimizing DRAM Controllers

+ **Continuous learning** in the presence of changing environment

+ **Reduced designer burden** in finding a good scheduling policy. Designer specifies:
  1) What system variables might be useful
  2) What target to optimize, but not how to optimize it

-- How to specify **different objectives**? (e.g., fairness, QoS, ...)

-- **Hardware complexity**?

-- Design **mindset** and flow

Executive Summary

• **Background**: Prefetchers predict addresses of future memory requests by associating memory access patterns with program context (called feature).

• **Problem**: Three key shortcomings of prior prefetchers:
  - Predict mainly using a single program feature
  - Lack inherent system awareness (e.g., memory bandwidth usage)
  - Lack in-silicon customizability

• **Goal**: Design a prefetching framework that:
  - Learns from multiple features and inherent system-level feedback
  - Can be customized in silicon to use different features and/or prefetching objectives

• **Contribution**: Pythia, which formulates prefetching as reinforcement learning problem
  - Takes adaptive prefetch decisions using multiple features and system-level feedback
  - Can be customized in silicon for target workloads via simple configuration registers
  - Proposes a realistic and practical implementation of RL algorithm in hardware

• **Key Results**:
  - Evaluated using a wide range of workloads from SPEC CPU, PARSEC, Ligra, Cloudsuite
  - Outperforms best prefetcher (in 1-core config.) by **3.4%**, **7.7%** and **17%** in 1/4/bw-constrained cores
  - Up to **7.8% more performance** over basic Pythia across Ligra workloads via simple customization

[SAFARI](https://github.com/CMU-SAFARI/Pythia)
Key Shortcomings in Prior Prefetchers

• We observe three key shortcomings that significantly limit performance benefits of prior prefetchers.

1. Predict mainly using a single program feature.

2. Lack inherent system awareness.

3. Lack in-silicon customizability.
A prefetching framework that can:

1. Learn to prefetch using multiple features and inherent system-level feedback information

2. Be easily customized in silicon to use different features and/or change prefetcher’s objectives
Our Proposal

Pythia

Formulates prefetching as a reinforcement learning problem

Pythia is named after the oracle of Delphi, who is known for her accurate prophecies. [https://en.wikipedia.org/wiki/Pythia](https://en.wikipedia.org/wiki/Pythia)
Basics of Reinforcement Learning (RL)

• Algorithmic approach to learn to take an action in a given situation to maximize a numerical reward

Agent

Environment

• Agent stores Q-values for every state-action pair
  - Expected return for taking an action in a state
  - Given a state, selects action that provides highest Q-value
Formulating Prefetching as RL

Prefetcher
Processor & Memory Subsystem

Features of memory request to address (e.g., PC)

Reward

Prefetch from address $A+o$ff set ($O$)
Pythia Overview

- **Q-Value Store**: Records Q-values for all state-action pairs
- **Evaluation Queue**: A FIFO queue of recently-taken actions
Simulation Methodology

- **Champsim** [3] trace-driven simulator

- **150** single-core memory-intensive workload traces
  - SPEC CPU2006 and CPU2017
  - PARSEC 2.1
  - Ligra
  - Cloudsuite

- Homogeneous and heterogeneous multi-core mixes

- **Five** state-of-the-art prefetchers
  - SPP [Kim+, MICRO’16]
  - Bingo [Bakhshalipour+, HPCA’19]
  - MLOP [Shakerinava+, 3rd Prefetching Championship, 2019 ]
  - SPP+DSPatch [Bera+, MICRO’19]
  - SPP+PPF [Bhatia+, ISCA’20]

Basic Pythia Configuration

• Derived from automatic design-space exploration

• **State:** 2 features
  - PC+Delta
  - Sequence of last-4 deltas

• **Actions:** 16 prefetch offsets
  - Ranging between -6 to +32. Including 0.

• **Rewards:**
  - $R_{AT} = +20$; $R_{AL} = +12$; $R_{NP-H} = -2$; $R_{NP-L} = -4$
  - $R_{IN-H} = -14$; $R_{IN-L} = -8$; $R_{CL} = -12$
Performance with Varying Core Count

![Graph showing performance with varying core count]

- **Geomean speedup over no prefetching**
- **Number of cores**

**Graph Details**
- **3.4%** increase in speedup for Bingo
- **7.7%** increase in speedup for Pythia

**Performance Tools**
- Pythia
- SPP
- MLOP
- Bingo

**SAFARI**
1. Pythia consistently provides the highest performance in **all core configurations**

2. Pythia’s gain increases with core count
Performance with Varying DRAM Bandwidth

Performance with Varying DRAM Bandwidth

Pythia outperforms prior best prefetchers for a wide range of DRAM bandwidth configurations.
Pythia’s Overhead

• **25.5 KB** of total metadata storage per core
  - Only simple tables

• We also model functionally-accurate Pythia with full complexity in **Chisel** [4] HDL

- 1.03% area overhead
- 0.4% power overhead
- Satisfies prediction latency of a desktop-class 4-core Skylake processor (Xeon D2132IT, 60W)

More in the Paper

• Performance comparison with unseen traces
  - Pythia provides equally high performance benefits

• Comparison against multi-level prefetchers
  - Pythia outperforms prior best multi-level prefetchers

Sibyl: Adaptive and Extensible Data Placement in Hybrid Storage Systems Using Online Reinforcement Learning

Gagandeep Singh, Rakesh Nadig, Jisung Park, Rahul Bera, Nastaran Hajinazar, David Novo, Juan Gómez-Luna, Onur Mutlu
Executive Summary

**Background:** Hybrid storage systems (HSSs) complement different storage technologies to extend the overall capacity and reduce the system cost with minimal effect on the application performance.

**Problem:** Accurately identify the performance-critical data of an application and placing it in the “best-fit” storage device. Three key shortcomings of prior data placement policies (heuristic-based and supervised learning-based) of hybrid storage systems:
- Lack of **adaptability**
- Lack of **device awareness** (e.g., read/write latencies of each device)
- Lack of **extensibility**

**Goal:** Develop a new, efficient, and high performance data-placement mechanism for hybrid storage systems that can:
- Dynamically derive an adaptive data-placement strategy by **continuously learning and adapting** to the application and underlying device characteristics.
- **Easily extensible** to incorporate a wide range of hybrid storage configurations.

**Key Idea:** Sibyl, an online reinforcement learning-based self-optimizing mechanism for data placement that:
- **Dynamically learns** from past experiences and **continuously adapts** its policy to improve long-term performance by interacting with the hybrid storage system.
- **Learns the asymmetry in the read/write latencies** present in modern hybrid storage devices while **taking into account** the inherent characteristics of an application.

**Key Results:** Sibyl is evaluated on a real system with multiple device configurations:
- Evaluated using a **wide range of workloads** from MSR Cambridge and Filebench.
- In a performance (cost) optimized hybrid storage configuration, Sibyl provides up to **21.6% (19.9%)** performance improvement compared to prior data placement policies.
- On a tri-hybrid storage system, Sibyl outperforms a heuristics-based policy by **23.9% -48.2%**
- Sibyl achieves **80%** performance of an oracle policy with storage overhead of **124.4 KiB**.
Hybrid Storage Systems
Key Shortcomings of Prior Data Placement Techniques

We observe **three key shortcomings** that significantly limit performance benefits of data-placement techniques.

- **Lack of adaptability**
- **Lack of device awareness**
- **Lack of extensibility**
Lack of Adaptability (1/2)

- Prior heuristic-based techniques consider only a few characteristics (e.g., access frequency) to perform data placement

- Statically tuned characteristics (based on fixed thresholds) are ineffective when used on a wide range of applications and system configurations

- Supervised learning techniques need labeled data and frequent retraining to adapt to varying workloads and system conditions

Prior techniques offer 41.1% lower performance compared to an Oracle policy
Lack of Adaptability (2/2)

CDE shows an average performance gap of 41.1% (32.6%) to Oracle for H&M (H&L)

HPS shows an average performance gap of 37.2% (55.5%) to Oracle for H&M (H&L)
Lack of Device Awareness

Prior data placement techniques:

- **do not adapt** well to changes in underlying device characteristics (e.g., storage read latency)

- **do not consider the data migration cost** between storage devices while making a data placement decision

- **are highly inefficient** in hybrid storage systems that have devices with significantly different read/write latencies
Lack of Extensibility

• Prior data placement techniques are typically designed for a hybrid storage system with only two storage devices.

• Significant effort is required to extend the data placement policies for more than two devices.

Compared to a RL-based solution, a heuristic-based policy provides 48.2% lower performance when extended from two to three devices.
Our Goal

A **data-placement mechanism** that can

- dynamically derive an adaptive data-placement strategy by **continuously learning** and **adapting** to the application and underlying device characteristics

- be **easily extended** to incorporate a wide range of hybrid storage configurations
Basics of Reinforcement Learning

• RL is a framework for decision making
  • An **autonomous agent observes** the current **state** of the environment
  • It **interacts** with the environment by taking **actions**
  • Agent is **rewarded** or **penalized** based on the consequences of its actions
  • Agent tries to maximize the cumulative reward
Applying RL to Data Placement

Key factors in applying RL for data placement in a hybrid storage system

• RL agent needs to be **aware of:**
  - asymmetry in read/write latencies of a storage device
  - differences in latencies across hybrid storage devices
  - application access patterns

• Data placement module should decide which actions to reward and penalize (credit assignment)

• Low implementation overhead
RL State

- Feature selection is performed to select only the most correlated features that affect data placement

- Divide the states into a small number of bins to reduce the state space

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
<th># of bins</th>
<th>Encoding (bits)</th>
</tr>
</thead>
<tbody>
<tr>
<td>$size_t$</td>
<td>Size of the requested page (in pages)</td>

<td>8</td>
<td>8</td>
</tr>
<tr>
<td>$curr_t$</td>
<td>Current placement of the requested page (fast/slow)</td>
<td>2</td>
<td>4</td>
</tr>
</tbody>
</table>
Reward

• For every action at time-step $t$, Sibyl gets a reward from the environment at time-step $t + 1$
• **Reward** acts as a feedback to the agent’s past action
• **Request latency** faithfully captures the status of the hybrid storage system
• **Penalty** value is chosen to prevent the agent from aggressively servicing all the requests from the faster device

$$R = \begin{cases} \frac{1}{L_t} & \text{if no eviction} \\ \max(0, \frac{1}{L_t} - R_p) & \text{if an eviction happens} \end{cases}$$

$L_t =$ latency of the request  
$R_p =$ eviction penalty
Overview of Sibyl

The two threads run asynchronously to prevent training delay from affecting the inference time.
Hyper-parameter Tuning

- Different hyper-parameter configurations were chosen using the design of experiments (DoE) technique

<table>

</tr>
</tbody>
</table>
Evaluation Methodology

• Evaluated on a real system with different hybrid storage configurations
• Hybrid storage system constitutes one contiguous logical block address space
• A custom block driver was implemented to manage the I/O requests to the storage devices
• We evaluate three different hybrid storage configurations
  - Performance-optimized (H&M)
  - Cost-optimized (H&L)
  - Tri-hybrid storage system

Evaluation Methodology

• 18 different workloads from MSR Cambridge and FileBench suites

• Sibyl is compared against **four baselines**
  - Heuristic-based policies
    • Cold data eviction (CDE) [Matsui et. al., “Design of Hybrid SSDs With Storage Class Memory and NAND Flash Memory,” IEEE 2017]
    • History Page Scheduler (HPS) [Meswani et.al., "Heterogeneous Memory Architectures: A HW/SW Approach for Mixing Die-stacked and Off-package Memories," HPCA, 2015]
  - Supervised learning-based policies
    • Recurrent neural network (RNN)-based technique adapted from Kleio [Doudali et.al., “Kleio: A Hybrid Memory Page Scheduler with Machine Intelligence,” HPDC, 2019]
Latency Improvement

Latency in Tri-Hybrid System

Sibyl outperforms the heuristic-based data placement policy for tri-hybrid system by 48.2% on average across all workloads.
Latency for Unseen Workloads

In H&M (H&L) configurations, Sibyl outperforms RNN-HSS and Archivist by 46.1% (54.6%) and 8.5% (44.1%) respectively.
Sensitivity to Fast Storage Capacity

(a) H&M

(b) H&L

Available capacity in fast storage

Normalized Average Request Latency

CDE  HPS  Archivist  RNN-HSS  Sibyl  Oracle
Sensitivity to Fast Storage Capacity

Sibyl consistently provides highest performance by dynamically adapting its data-placement policy.
Overhead Analysis

• **Performance Overhead**
  - *~10ns* for every inference on the evaluated system; this is several orders of magnitude less than I/O latency of high-end SSD

• **Implementation Overhead**
  - 124.4 KiB of implementation overhead

• **Metadata overhead**
  - 0.1% of the total storage capacity when using a 4 KiB data placement granularity
  - 40-bit metadata overhead per data placement unit

An Intelligent Architecture

- Data-driven
  - Machine learns the “best” policies (how to do things)

- Sophisticated, workload-driven, changing, far-sighted policies

- Automatic data-driven policy learning

- All controllers are intelligent data-driven agents

We need to rethink design (of all controllers)
Challenge and Opportunity for Future

Data-Driven (Self-Optimizing) Computing Architectures
Data-Aware Architectures
Architectures are terrible at dealing with data
- Designed to mainly store and move data vs. to compute
- They are processor-centric as opposed to data-centric

Architectures are terrible at taking advantage of vast amounts of data (and metadata) available to them
- Designed to make simple decisions, ignoring lots of data
- They make human-driven decisions vs. data-driven decisions

Architectures are terrible at knowing and exploiting different properties of application data
- Designed to treat all data as the same
- They make component-aware decisions vs. data-aware
Data-Aware Architectures

- A data-aware architecture understands what it can do with and to each piece of data

- It makes use of different properties of data to improve performance, efficiency and other metrics
  - Compressibility
  - Approximability
  - Locality
  - Sparsity
  - Criticality for Computation
  - Access Semantics
  - ...

†‡Simon Fraser University
SW provides key program information to HW

Data Structures
Access Patterns
Data Type/Layout

Software
Hardware

Data Placement
Prefetcher
Data Compression
Broader goal: Enable many cross-layer optimizations

Express:
- Data structures
- Access semantics
- Data types
- Working set
- Reuse
- Access frequency
  ...

Optimizations:
- Cache Management
- Data Placement in DRAM
- Data Compression
- Approximation
- DRAM Cache Management
- NVM Management
- NUCA/NUMA
  ...

Benefits:
- More efficient HW:
  - Performance
- Reduced SW burden:
  - Programmability
  - Portability
Our approach: Rich cross-layer abstractions

1. Generality: Enable a wide range of cross-layer approaches
2. Minimize programmer effort
3. Overhead

Approach: Flexibly associate specific semantic information with any data & code
Example: XMem

- **Goal**: convey data semantics to the hardware enables more intelligent management of resources.
- **XMem**: introduces a new HW/SW abstraction, called *Atom*, for conveying data semantics

---

Vijaykumar+, "A Case for Richer Cross-layer Abstractions: Bridging the Semantic Gap with Expressive Memory", ISCA 2018
XMem Aids/Enables Many Optimizations

Table 1: Summary of the example memory optimizations that XMem aids.

<table>
<thead>
<tr>
<th>Memory optimization</th>
<th>Example semantics provided by XMem (described in §3.3)</th>
<th>Example Benefits of XMem</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cache management</td>
<td>(i) Distinguishing between data structures or pools of similar data; (ii) Working set size; (iii) Data reuse</td>
<td>Enables: (i) applying different caching policies to different data structures or pools of data; (ii) avoiding cache thrashing by knowing the active working set size; (iii) bypassing/prioritizing data that has no/high reuse. (§5)</td>
</tr>
<tr>
<td>Page placement in DRAM e.g., [23, 24]</td>
<td>(i) Distinguishing between data structures; (ii) Access pattern; (iii) Access intensity</td>
<td>Enables page placement at the data structure granularity to (i) isolate data structures that have high row buffer locality and (ii) spread out concurrently-accessed irregular data structures across banks and channels to improve parallelism. (§6)</td>
</tr>
<tr>
<td>Cache/mem compression e.g., [25–32]</td>
<td>(i) Data type: integer, float, char; (ii) Data properties: sparse, pointer, data index</td>
<td>Enables using a different compression algorithm for each data structure based on data type and data properties, e.g., sparse data encodings, FP-specific compression, delta-based compression for pointers [27].</td>
</tr>
<tr>
<td>Data prefetching e.g., [33–36]</td>
<td>(i) Access pattern: strided, irregular, irregular but repeated (e.g., graphs), access stride; (ii) Data type: index, pointer</td>
<td>Enables (i) highly accurate software-driven prefetching while leveraging the benefits of hardware prefetching (e.g., by being memory bandwidth-aware, avoiding cache thrashing); (ii) using different prefetcher types for different data structures: e.g., stride [33], tile-based [20], pattern-based [34–37], data-based for indices/pointers [38, 39], etc.</td>
</tr>
<tr>
<td>DRAM cache management e.g., [40–46]</td>
<td>(i) Access intensity; (ii) Data reuse; (iii) Working set size</td>
<td>(i) Helps avoid cache thrashing by knowing working set size [44]; (ii) Better DRAM cache management via reuse behavior and access intensity information.</td>
</tr>
<tr>
<td>Approximation in memory e.g., [47–53]</td>
<td>(i) Distinguishing between pools of similar data; (ii) Data properties: tolerance towards approximation</td>
<td>Enables (i) each memory component to track how approximable data is (at a fine granularity) to inform approximation techniques; (ii) data placement in heterogeneous reliability memories [54].</td>
</tr>
<tr>
<td>Data placement: NUMA systems e.g., [55, 56]</td>
<td>(i) Data partitioning across threads (i.e., relating data to threads that access it); (ii) Read-Write properties</td>
<td>Reduces the need for profiling or data migration (i) to co-locate data with threads that access it and (ii) to identify Read-Only data, thereby enabling techniques such as replication.</td>
</tr>
<tr>
<td>Data placement: hybrid memories e.g., [16, 57, 58]</td>
<td>(i) Read-Write properties (Read-Only/Read-Write); (ii) Access intensity; (iii) Data structure size; (iv) Access pattern</td>
<td>Avoids the need for profiling/migration of data in hybrid memories to (i) effectively manage the asymmetric read-write properties in NVM (e.g., placing Read-Only data in the NVM) [16, 57]; (ii) make tradeoffs between data structure &quot;hotness&quot; and size to allocate fast/high bandwidth memory [14]; and (iii) leverage row-buffer locality in placement based on access pattern [45].</td>
</tr>
<tr>
<td>Managing NUCA systems e.g., [15, 59]</td>
<td>(i) Distinguishing pools of similar data; (ii) Access intensity; (iii) Read-Write or Private-Shared properties</td>
<td>(i) Enables using different cache policies for different data pools (similar to [15]); (ii) Reduces the need for reactive mechanisms that detect sharing and read-write characteristics to inform cache policies.</td>
</tr>

Phillip B. Gibbons† Onur Mutlu§†
†Carnegie Mellon University ‡NVIDIA §ETH Zürich
Locality Descriptor: Executive Summary

Exploiting data locality in GPUs is a challenging task.

Flexible, architecture-agnostic interface

Performance Benefits:
26.6% (up to 46.6%) from cache locality
53.7% (up to 2.8x) from NUMA locality
An Example: Hybrid Memory Management

Hardware/software manage data allocation and movement to achieve the best of multiple technologies

Yoon+, “Row Buffer Locality Aware Caching Policies for Hybrid Memories,” ICCD 2012 Best Paper Award.
An Example: Heterogeneous-Reliability Memory

- Yixin Luo, Sriram Govindan, Bikash Sharma, Mark Santaniello, Justin Meza, Aman Kansal, Jie Liu, Badriddine Khessib, Kushagra Vaid, and Onur Mutlu, "Characterizing Application Memory Error Vulnerability to Optimize Data Center Cost via Heterogeneous-Reliability Memory"
  Proceedings of the 44th Annual IEEE/IFIP International Conference on Dependable Systems and Networks (DSN), Atlanta, GA, June 2014. [Summary] [Slides (pptx) (pdf)] [Coverage on ZDNet]
Exploiting Memory Error Tolerance with Hybrid Memory Systems

- **Vulnerable data**
- **Tolerant data**
- **Reliable memory**
- **Low-cost memory**

On Microsoft’s Web Search workload:
- Reduces server hardware **cost** by **4.7 %**
- Achieves single server **availability** target of **99.90 %**

**Heterogeneous-Reliability Memory** [DSN 2014]
Heterogeneous-Reliability Memory

Step 1: Characterize and classify application memory error tolerance

Step 2: Map application data to the HRM system enabled by SW/HW cooperative solutions

Proceedings of the 44th Annual IEEE/IFIP International Conference on Dependable Systems and Networks (DSN), Atlanta, GA, June 2014. [Summary] [Slides (pptx) (pdf)] [Coverage on ZDNet]
Data-Aware Cross-Layer Hybrid System Management

- Heterogeneous agents: CPUs, GPUs, and HWAs
- Main memory interference between CPUs, GPUs, HWAs
- Many timing constraints for various memory types
- Many goals at the same time: performance, fairness, QoS, energy efficiency, ...
Another Example: EDEN for DNNs

- Deep Neural Network evaluation is very DRAM-intensive (especially for large networks)

1. Some data and layers in DNNs are very tolerant to errors

2. Reduce DRAM latency and voltage on such data and layers

3. While still achieving a user-specified DNN accuracy target by making training DRAM-error-aware

Data-aware management of DRAM latency and voltage for Deep Neural Network Inference
Example DNN Data Type to DRAM Mapping

Mapping example of ResNet-50:

Map more error-tolerant DNN layers to DRAM partitions with lower voltage/latency

4 DRAM partitions with different error rates
Key idea: Enable **accurate, efficient** DNN inference using approximate DRAM

EDEN is an **iterative** process that has 3 **key steps**
CPU: DRAM Energy Evaluation

Average 21% DRAM energy reduction maintaining accuracy within 1% of original
CPU: Performance Evaluation

Average **8%** system speedup
Some workloads achieve **17%** speedup

EDEN achieves **close to the ideal** speedup possible via tRCD scaling
GPU, Eyeriss, and TPU: Energy Evaluation

- **GPU**: average 37% energy reduction
- **Eyeriss**: average 31% energy reduction
- **TPU**: average 32% energy reduction

Challenge and Opportunity for Future

Data-Aware (Expressive) Computing Architectures
We Need to **Rethink** the Entire Stack

We can get there case by case
Principled Architectures & What They Can Enable
A Quote from A Famous Architect

- “architecture [...] based upon principle, and not upon precedent”
Precedent-Based Design?

- “architecture [...] based upon principle, and not upon precedent”
Principled Design

- “architecture [...] based upon principle, and not upon precedent”
Organic architecture is a philosophy of architecture which promotes harmony between human habitation and the natural world through design approaches so sympathetic and well integrated with its site, that buildings, furnishings, and surroundings become part of a unified, interrelated composition.

A well-known example of organic architecture is Fallingwater, the residence Frank Lloyd Wright designed for the Kaufmann family in rural Pennsylvania. Wright had many choices to locate a home on this large site, but chose to place the home directly over the waterfall and creek creating a close, yet noisy dialog with the rushing water and the steep site. The horizontal striations of stone masonry with daring cantilevers of colored beige concrete blend with native rock outcroppings and the wooded environment.
Another Example: Precedent-Based Design

Another Principled Design
Principle Applied to Another Structure
The Overarching Principle

**Zoomorphic architecture**

From Wikipedia, the free encyclopedia

**Zoomorphic architecture** is the practice of using animal forms as the inspirational basis and blueprint for architectural design. "While animal forms have always played a role adding some of the deepest layers of meaning in architecture, it is now becoming evident that a new strand of **biomorphism** is emerging where the meaning derives not from any specific representation but from a more general allusion to biological processes."[1]

Some well-known examples of Zoomorphic architecture can be found in the TWA Flight Center building in New York City, by Eero Saarinen, or the Milwaukee Art Museum by Santiago Calatrava, both inspired by the form of a bird’s wings.[3]

Research and Teaching in:

- Computer architecture, computer systems, hardware security, bioinformatics
- Memory and storage systems
- Hardware security, safety, predictability
- Fault tolerance
- Hardware/software cooperation
- Architectures for bioinformatics, health, medicine
- ...
Build fundamentally better architectures
Four Key Current Directions

- Fundamentally **Secure/Reliable/Safe** Architectures

- Fundamentally **Energy-Efficient** Architectures
  - Memory-centric (Data-centric) Architectures

- Fundamentally **Low-Latency and Predictable** Architectures

- Architectures for **AI/ML, Genomics, Medicine, Health**
The Transformation Hierarchy

Computer Architecture (expanded view)

Computer Architecture (narrow view)

Problem
Algorithm
Program/Language
System Software
SW/HW Interface
Micro-architecture
Logic
Devices
Electrons
To achieve the highest energy efficiency and performance:

**we must take the expanded view**

of computer architecture

---

**Co-design across the hierarchy:**

Algorithms to devices

**Specialize as much as possible within the design goals**
Current Research Mission & Major Topics

Build fundamentally better architectures

- Data-centric arch. for low energy & high perf.
  - Proc. in Mem/DRAM, NVM, unified mem/storage

- Low-latency & predictable architectures
  - Low-latency, low-energy yet low-cost memory
  - QoS-aware and predictable memory systems

- Fundamentally secure/reliable/safe arch.
  - Tolerating all bit flips; patchable HW; secure mem

- Architectures for ML/AI/Genomics/Health/Med
  - Algorithm/arch./logic co-design; full heterogeneity

- Data-driven and data-aware architectures
  - ML/AI-driven architectural controllers and design
  - Expressive memory and expressive systems

SAFARI Project & Seminars Courses (Spring 2021)

Welcome to the wiki for Project and Seminar courses SAFARI offers.

Courses we offer:

- Understanding and Improving Modern DRAM Performance, Reliability, and Security with Hands-On Experiments
- Designing and Evaluating Memory Systems and Modern Software Workloads with Ramulator
- Accelerating Genome Analysis with FPGAs, GPUs, and New Execution Paradigms
- Genome Sequencing on Mobile Devices
- Exploring the Processing-in-Memory Paradigm for Future Computing Systems
- Hands-on Acceleration on Heterogeneous Computing Systems
- Understanding and Designing Modern NAND Flash-Based Solid-State Drives (SSDs) by Building a Practical SSD Simulator
PIM Course (Current)

- **Fall 2021 Edition:**

- **Youtube Livestream:**
  - [https://www.youtube.com/watch?v=9e4Chnwdovo&list=PL5Q2soXY2Zi-841fUYYUK9EsXKhQKRPyX](https://www.youtube.com/watch?v=9e4Chnwdovo&list=PL5Q2soXY2Zi-841fUYYUK9EsXKhQKRPyX)

- **Project course**
  - Taken by Bachelor’s/Master’s students
  - Processing-in-Memory lectures
  - Hands-on research exploration
  - Many research readings

Data-Centric and Data-Aware Frameworks for Fundamentally Efficient Data Handling in Modern Computer Systems
27 Sep 2021

Overview of Our Approach
Data and the efficient computation of data should be the ultimate priority of the system
- Data-Centric Architectures
  - Enable computation with minimal data movement
  - Compute where data resides
- Data-Aware Architectures
  - Understand what they can do with and to each piece of data
  - Make use of different properties of data to improve performance, efficiency, etc.

SAFARI Live Seminars in Computer Architecture
Damla Senol Cali, Bionano Genomics
Accelerating Genome Sequence Analysis via Efficient Hardware/Algorithm Co-Design
7 Sun Nov 2021

Our Goal & Approach
- Our Goal: Accelerating genome sequence analysis by efficient hardware/algorithm co-design
- Our Approach:
  - Analyze the multiple steps and the associated tools in the genome sequence analysis pipeline
  - Expose the tradeoffs between accuracy, performance, memory usage and scalability, and
  - Co-design fast and efficient algorithms along with scalable and energy-efficient customized hardware accelerators for the key bottleneck steps of the pipeline

COVIDHunter
An accurate and flexible COVID-19 outbreak simulation model that forecasts the strength of future mitigation measures and the numbers of cases, hospitalizations, and deaths for a given day, while considering the potential effect of environmental conditions. Described by Aizer et al. (preliminary version at [https://arxiv.org/abs/2006.02268](https://arxiv.org/abs/2006.02268)).

SNP-Selective-Hiding
An optimization-based mechanism to selectively hide the minimum number of overlapping SNPs among the family members who participated in the genomic studies (i.e., GWAS). Our goal is to distort the dependencies among the family members in the original database for achieving better privacy without significantly degrading the data utility.

SneakySnake
SneakySnake is the first and the only pre-alignment filtering algorithm that works efficiently and fast on modern CPU, FPGA, and GPU architectures. It greatly (by more than two orders of magnitude) expedites sequence alignment calculation for both short and long reads. Described in the Bioinformatics (2020) by Aizer et al. [https://arxiv.org/abs/2006.02268](https://arxiv.org/abs/2006.02268).

Fundamental Thinking
Historical: Opportunities at the Bottom

There's Plenty of Room at the Bottom

From Wikipedia, the free encyclopedia

"There's Plenty of Room at the Bottom: An Invitation to Enter a New Field of Physics" was a lecture given by physicist Richard Feynman at the annual American Physical Society meeting at Caltech on December 29, 1959.[1] Feynman considered the possibility of direct manipulation of individual atoms as a more powerful form of synthetic chemistry than those used at the time. Although versions of the talk were reprinted in a few popular magazines, it went largely unnoticed and did not inspire the conceptual beginnings of the field. Beginning in the 1980s, nanotechnology advocates cited it to establish the scientific credibility of their work.

https://en.wikipedia.org/wiki/There%27s_Plenty_of_Room_at_the_Bottom
Feynman considered some ramifications of a general ability to manipulate matter on an atomic scale. He was particularly interested in the possibilities of denser computer circuitry, and microscopes that could see things much smaller than is possible with scanning electron microscopes. These ideas were later realized by the use of the scanning tunneling microscope, the atomic force microscope and other examples of scanning probe microscopy and storage systems such as Millipede, created by researchers at IBM.

Feynman also suggested that it should be possible, in principle, to make nanoscale machines that "arrange the atoms the way we want", and do chemical synthesis by mechanical manipulation.

He also presented the possibility of "swallowing the doctor", an idea that he credited in the essay to his friend and graduate student Albert Hibbs. This concept involved building a tiny, swallowable surgical robot.
Historical: Opportunities at the Top

There’s plenty of room at the Top: What will drive computer performance after Moore’s law?

Charles E. Leiserson¹, Neil C. Thompson¹,², Joel S. Emer¹,³, Bradley C. Kuszmaul¹, Butler W. Lampson¹,⁴

+ See all authors and affiliations

Science 05 Jun 2020: Vol. 368, Issue 6495, eaam9744
DOI: 10.1126/science.aam9744

Much of the improvement in computer performance comes from decades of miniaturization of computer components, a trend that was foreseen by the Nobel Prize–winning physicist Richard Feynman in his 1959 address, “There’s Plenty of Room at the Bottom,” to the American Physical Society. In 1975, Intel founder Gordon Moore predicted the regularity of this miniaturization trend, now called Moore’s law, which, until recently, doubled the number of transistors on computer chips every 2 years.

Unfortunately, semiconductor miniaturization is running out of steam as a viable way to grow computer performance—there isn’t much more room at the “Bottom.” If growth in computing power stalls, practically all industries will face challenges to their productivity. Nevertheless, opportunities for growth in computing performance will still be available, especially at the “Top” of the computing-technology stack: software, algorithms, and hardware architecture.
Axiom, Revisited

There is plenty of room both at the top and at the bottom

but much more so

when you

communicate well between and optimize across

the top and the bottom
