Mathematical Modeling of Physical Systems

Bond Graphs for Mechanical Systems

- We shall look today in a bit more detail at the modeling of 1D mechanical systems using bond graphs.
- First, we shall look at the problem of holonomic constraints in mechanical systems.
- Then, we shall discuss how a wrapped mechanical bond graph library may be constructed.
- Finally, we shall look at a symbolic algorithm for state selection.

Mathematical Modeling of Physical Systems

State Variables in Mechanical Systems

- We have already seen that masses (inertias) can be modeled using bond graph inductors, whereas springs can be modeled using bond graph capacitors. Hence the natural state variables in a bond graph description of a mechanical system are the absolute (angular) velocities of the bodies and the spring forces (torques).
- In a model of a mechanical system described in this fashion, the (angular) positions are missing. They are not needed for a proper and complete description of the dynamics of the system.

Mathematical Modeling of Physical Systems

Holonomic Constraints

- This causes problems, as it is relevant to know whether two bodies occupy the same space at the same time, i.e., whether they bump into each other or not.
- Also, when two bodies are connected at a point (e.g. through a joint), it is insufficient to state that the *velocities* of these points are equal. It should be stated that their *positions* are identical.
- Such positional constraints are being referred to as *holonomic constraints* in the mechanical literature.
- The corresponding velocity constraints (non-holonomic constraints) don't need to be specified separately, because they can be derived automatically from the holonomic constraints.

November 8, 2012

© Prof. Dr. François E. Cellier

Start Presentation

Holonomic Constraints II

- For this reason, it may be better to find an alternate description that uses the *absolute velocities and positions of bodies* as state variables, leaving the spring forces out.
- Can this be done within the framework of the bond graph methodology?
- It can, and this is how the two wrapped 1D mechanical bond graph libraries (for translational and rotational motions) have been built.

November 8, 2012

© Prof. Dr. François E. Cellier

Start Presentation

The Mechanical Connectors

- We introduce two translational flange connectors. These are similar to those of the standard library, but they are not identical, as they shall contain a second across variable: the velocity, v .
- Hence our mechanical models will be *incompatible with those of the standard library*.
- The two flange models are actually identical. They are both offered for optical reasons only.

November 8, 2012

© Prof. Dr. François E. Cellier

Start Presentation

The Mechanical Connectors II

- We also need a real signal connector. This is similar to the input and output connectors of the blocks library, but the signal is bidirectional, rather than being unidirectional.

November 8, 2012

© Prof. Dr. François E. Cellier

Start Presentation

The Wrapper Models

- We need wrapper models that convert the mechanical connectors to bond graph connectors and back.
- Since the bond graph connector cannot include the positional information, this must be separated out into a second signal connector.

November 8, 2012

© Prof. Dr. François E. Cellier

Start Presentation

The Wrapper Models II

- Since the mechanical connector corresponds to a mechanical node, i.e., a point where the sum of all forces (torques) adds up to zero, it corresponds to a bond graph 1-junction, rather than to a bond graph 0-junction. Consequently, it is here the effort variable that must get the negative sign.

November 8, 2012

Start Presentation

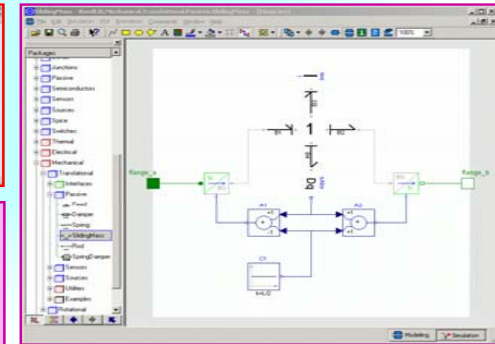

The Sliding Mass Model

- We are now ready to look at the model of a sliding mass.

The two state variables are the f variable of the inductor model and the output of the internal integrator of the q sensor.

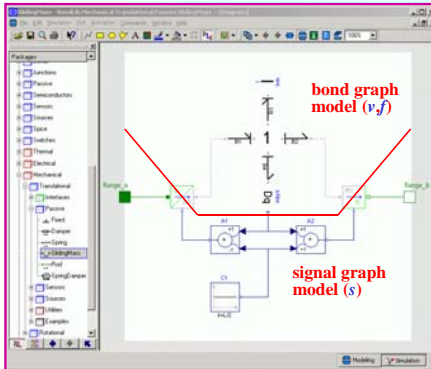

November 8, 2012

© Prof. Dr. François E. Cellier

Start Presentation

The Sliding Mass Model II

The model is split into an upper (bond graph) part that deals with velocities and forces, and a lower (signal) part that deals with positional information.

The position s calculated by the sensor is the position of the center of the mass bar.

The position of the left connector is $L/2$ to the left of the center, and the position of the right connector is $L/2$ to the right of the center.

These positional values are distributed out to the left and to the right through the mechanical connectors

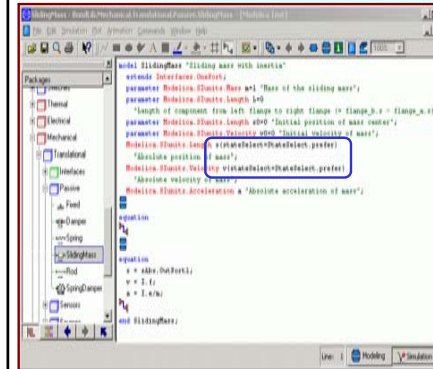

November 8, 2012

© Prof. Dr. François E. Cellier

Start Presentation

The Sliding Mass Model III

The natural state variables of this model are the internal variables I_f and $sAbs.Integrator1.y$. This is inconvenient.

The user of the model would prefer to use the local variables v and s of the mass model as state variables.

Dymola can be told to modify the equations such that, if possible, the desired variables are being used as state variables, i.e., show up in the simulation code with a $der()$ operator.

We shall discuss later in this lecture, how this can actually be accomplished.

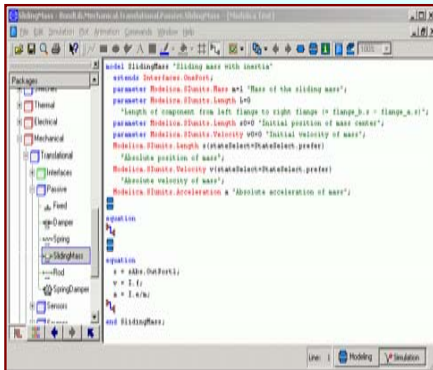

November 8, 2012

© Prof. Dr. François E. Cellier

Start Presentation

The Sliding Mass Model IV

One question that remains is, for which variables we now have to specify the *initial conditions*.

Do we do it for the new state variables s and v , or do we still do it for the natural state variables?

It turns out that we can do either or, but not both.

Dymola will use the specified values as *start values of an iteration* and iterate on the unknown initial values of the new state variables, until it finds a set of initial conditions that is consistent with the information that has been specified by the user.

November 8, 2012

Start Presentation

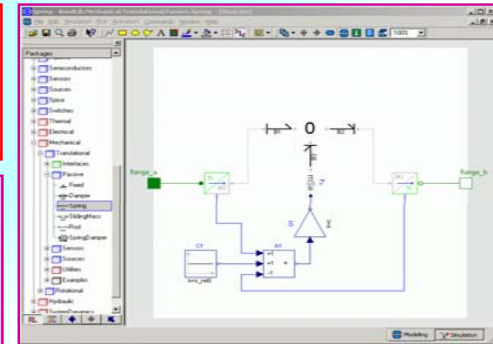

The Spring Model

- We are now ready to look at the model of a spring.

The spring is modeled as a modulated effort source, i.e., without an integrator of its own. It imports the positional information through its two terminals.

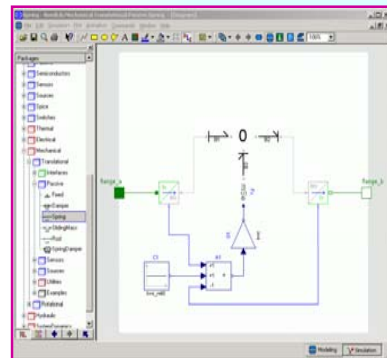

November 8, 2012

© Prof. Dr. François E. Cellier

Start Presentation

The Spring Model II

The spring can be either described using the equation:

$$f_x = k \cdot (x_{\text{left}} - x_{\text{right}})$$

or using the differentiated form:

$$df_x/dt = k \cdot (v_{\text{left}} - v_{\text{right}})$$

Until now, we always used the latter representation, i.e., a capacitor, whereas now, we are using the former equation.

Both work equally well, in principle.

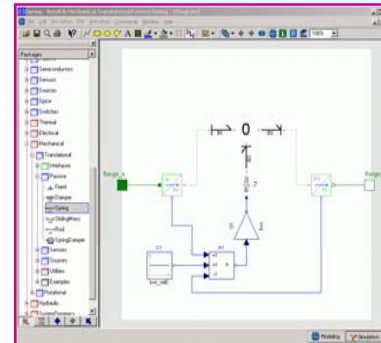

November 8, 2012

© Prof. Dr. François E. Cellier

Start Presentation

The Spring Model III

There is however a problem.

The new spring model imports the needed positional information through its two terminals.

Since positional information is only computed by masses and inertial frames, this spring model can only be placed either between two masses or between a mass and the ground.

In particular, it is not possible to place a spring and a damper in series with each other.

(Placing two springs in series would have worked correctly if we had used a-causal models for signal processing rather than relying on the causal blocks from the block library.)

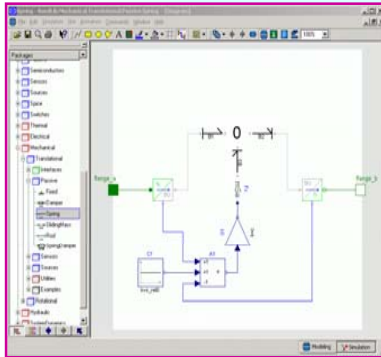

November 8, 2012

© Prof. Dr. François E. Cellier

Start Presentation

The Spring Model IV

The former model (using a capacitor) did not share this limitation.

Hence our new spring model is a bit of a dirty trick.

... the same dirty trick by the way that the standard library is using, albeit without offering a bond graph interpretation.

November 8, 2012

© Prof. Dr. François E. Cellier

[Start Presentation](#)

The Spring Model V

The equation layer doesn't offer any surprises.

The relative position and velocity of the spring are calculated here, since these are variables that the user may like to display.

The remaining models of the library are what we would expect them to be, thus they don't need to be discussed here.

November 8, 2012

© Prof. Dr. François E. Cellier

[Start Presentation](#)

Wrapping Tightly – Protected Variables

Let's now look at the *expanded view* of the equation layer of the spring model.

I manually placed the keyword **protected** in front of the declarations of variables to the inside of the wrapper models.

The effect of this measure is to prevent these variables from being displayed in the *simulation window*.

In this way, the model parameters will look exactly the same in the simulation window as using the corresponding model of the standard library.

The model has been *wrapped tightly*.

Mathematical Modeling of Physical Systems

The Selection of State Variables

- Until now, we have always used the “capacitor” voltages and “inductor” currents of our bond graph models as our state variables.
- Sometimes, this is not desirable. We may have specific wishes as to which variables should be used as state variables.
- In some cases (as we shall see later), the choice of state variables also influences the run-time efficiency of the generated simulation code.
- The number of generated equations may depend heavily on a wise choice of state variables.

Mathematical Modeling of Physical Systems

The Selection of State Variables II

- Dymola** supports the concept of selecting state variables differently from those that the system would normally choose.
- To this end, the user declares a desired state variable as follows:

$$Real\ x(stateSelect = StateSelect.prefer)$$
- Dymola** complies with the request by means of a variant of the **Pantelides algorithm**.

November 8, 2012

↔

The Selection of State Variables III

- If the desired state variable already appears in differentiated form, use it whenever possible as a state.
- If the desired state variable does not already appear in differentiated form, differentiate the equation that computes the desired state, add it to the set of equations, and create a new integrator for it.
- We now have one equation too many.
- If in the process of differentiation additional algebraic variables are being differentiated, differentiate the equations defining those variables as well, add them also to the set of equations, but don't add new integrators for them.

November 8, 2012

© Prof. Dr. François E. Cellier

Start Presentation

The Selection of State Variables IV

- In the process of these additional differentiations, new variables and new equations are added to the set, so that at the end of the process, there is still one equation too many.
- If the desired state variable is legitimate, at least one of the previous state variables occurs among the set of equations that were differentiated.
- Throw the integrator associated with one of those state variables away to once again end up with an identical number of equations and unknowns.

November 8, 2012

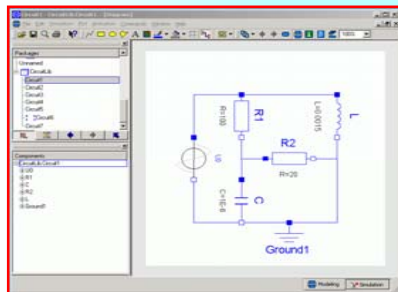

© Prof. Dr. François E. Cellier

Start Presentation

The Selection of State Variables V

- Given our “standard” electrical circuit.
- We have already learnt how to retrieve a causal set of equations from it.

- 1: $U_0 = f(t)$
- 2: $v_2 = u_C$
- 3: $u_{R2} = u_C$
- 4: $u_L = U_0$
- 5: $v_1 = U_0$
- 6: $i_{R2} = u_{R2} / R_2$
- 7: $u_{R1} = v_1 - v_2$
- 8: $i_{R1} = u_{R1} / R_1$
- 9: $i_C = i_{R1} - i_{R2}$
- 10: $i_0 = i_L + i_{R1}$
- 11: $di_L/dt = u_L / L_1$
- 12: $du_C/dt = i_C / C_1$

November 8, 2012

© Prof. Dr. François E. Cellier

Start Presentation

The Selection of State Variables VI

- We wish to derive a different set of simulation equations that uses u_{R1} as a state variable, while eliminating one of the two former state variables from the set.
- To this end, we manually implement the state selection algorithm described earlier.

Mathematical Modeling of Physical Systems

The Selection of State Variables VII

Continue with this equation.

Now differentiate these two equations.

Differentiate this equation, while creating a new derivative for u_{R1} , but no new derivatives for v_1 and v_2 .

Eliminate this integrator.

- $U_0 = f(t)$
- $v_2 = u_C$
- $u_{R2} = u_C$
- $u_L = U_0$
- $v_1 = U_0$
- $i_{R2} = u_{R2} / R_2$
- $u_{R1} = v_1 - v_2$
- $i_{R1} = u_{R1} / R_1$
- $i_C = i_{R1} - i_{R2}$
- $i_0 = i_L + i_{R1}$
- $di_L/dt = u_L / L_1$
- $du_C/dt = i_C / C_1$

$du_{R1}/dt = dv_1 - dv_2$
 $dv_1 = dU_0$
 $dv_2 = du_C$
 $dU_0 = df(t)/dt$
