# A Curious Phenomenon

# Modern DRAM is Prone to Disturbance Errors

Repeatedly reading a row enough times (before memory gets refreshed) induces **disturbance errors** in adjacent rows in **most real DRAM chips you can buy today**

# Most DRAM Modules Are Vulnerable

A company

Up to  
 $1.0 \times 10^7$   
errors

B company

Up to  
 $2.7 \times 10^6$   
errors

C company

Up to  
 $3.3 \times 10^5$   
errors

# Recent DRAM Is More Vulnerable

# Why Is This Happening?

---

- DRAM cells are too close to each other!
  - They are not electrically isolated from each other
- Access to one cell affects the value in nearby cells
  - due to **electrical interference** between
    - the cells
    - wires used for accessing the cells
  - Also called cell-to-cell coupling/interference
- Example: When we activate (apply high voltage) to a row, an adjacent row gets slightly activated as well
  - Vulnerable cells in that slightly-activated row lose a little bit of charge
  - If RowHammer happens enough times, charge in such cells gets drained

# Higher-Level Implications

- This simple circuit level failure mechanism has enormous implications on upper layers of the transformation hierarchy

# A Simple Program Can Induce Many Errors

```
loop:  
  mov  (X), %eax  
  mov  (Y), %ebx  
  clflush (X)  
  clflush (Y)  
  mfence  
  jmp  loop
```

# A Simple Program Can Induce Many Errors

1. Avoid *cache hits*
  - Flush **X** from cache
2. Avoid *row hits* to **X**
  - Read **Y** in another row

# A Simple Program Can Induce Many Errors

```
loop:  
  mov  (X), %eax  
  mov  (Y), %ebx  
  clflush (X)  
  clflush (Y)  
  mfence  
  jmp  loop
```

  - <https://www.memtest86.com/troubleshooting.htm#hammer>

## Why am I only getting errors during Test 13 Hammer Test?

The Hammer Test is designed to detect RAM modules that are susceptible to disturbance errors caused by charge leakage. This phenomenon is characterized in the research paper **Flipping Bits in Memory Without Accessing Them: An Experimental Study of DRAM Disturbance Errors** by Yoongu Kim et al. According to the research, a significant number of RAM modules manufactured 2010 or newer are affected by this defect. In simple terms, susceptible RAM modules can be subjected to disturbance errors when repeatedly accessing addresses in the same memory bank but different rows in a short period of time. Errors occur when the repeated access causes charge loss in a memory cell, before the cell contents can be refreshed at the next DRAM refresh interval.

Starting from MemTest86 v6.2, the user may see a warning indicating that the RAM may be vulnerable to high frequency row hammer bit flips. This warning appears when errors are detected during the first pass (maximum hammer rate) but no errors are detected during the second pass (lower hammer rate). See **MemTest86 Test Algorithms** for a description of the two passes that are performed during the Hammer Test (Test 13). When performing the second pass, address pairs are hammered only at the rate deemed as the maximum allowable by memory vendors (200K accesses per 64ms). Once this rate is exceeded, the integrity of memory contents may no longer be guaranteed. If errors are detected in both passes, errors are reported as normal.

The errors detected during Test 13, albeit exposed only in extreme memory access cases, are most certainly real errors. During typical home PC usage (eg. web browsing, word processing, etc.), it is less likely that the memory usage pattern will fall into the extreme case that make it vulnerable to disturbance errors. It may be of greater concern if you were running highly sensitive equipment such as medical equipment, aircraft control systems, or bank database servers. It is impossible to predict with any accuracy if these errors will occur in real life applications. One would need to do a major scientific study of 1000 of computers and their usage patterns, then do a forensic analysis of each application to study how it makes use of the RAM while it executes. To date, we have only seen 1-bit errors as a result of running the Hammer Test.

# First Adopters: Memory Testing Software

- PassMark Software, memtest86, since 2014
  - <https://www.memtest86.com/troubleshooting.htm#hammer>

## Detection and mitigation of row hammer errors

The ability of MemTest86 to detect and report on row hammer errors depends on several factors and what mitigations are in place. To generate errors adjacent memory rows must be repeatedly accessed. But hardware features such as multiple channels, interleaving, **scrambling**, Channel Hashing, NUMA & XOR schemes make it nearly impossible (for an arbitrary CPU & RAM stick) to know which memory addresses correspond to which rows in the RAM. Various mitigations might also be in place. Different BIOS firmware might set the refresh interval to different values (tREFI). The shorter the interval the more resistant the RAM will be to errors. But shorter intervals result in higher power consumption and increased processing overhead. Some CPUs also support pseudo target row refresh (pTRR) that can be used in combination with pTRR-compliant RAM. This field allows the RAM stick to indicate the MAC (Maximum Active Count) level which is the RAM can support. A typical value might be 200,000 row activations. Some CPUs also support the Joint Electron Design Engineering Council (JEDEC) Targeted Row Refresh (TRR) algorithm. The TRR is an improved version of the previously implemented pTRR algorithm and does not inflict any performance drop or additional power usage. As a result the row hammer test implemented in MemTest86 maybe not be the worst case possible and vulnerabilities in the underlying RAM might be undetectable due to the mitigations in place in the BIOS and CPU.

Exploiting the DRAM rowhammer bug to gain kernel privileges

# RowHammer Security Attack Example

---

- “Rowhammer” is a problem with some recent DRAM devices in which repeatedly accessing a row of memory can cause bit flips in adjacent rows (Kim et al., ISCA 2014).
  - Flipping Bits in Memory Without Accessing Them: An Experimental Study of DRAM Disturbance Errors (Kim et al., ISCA 2014)
- We tested a selection of laptops and found that a subset of them exhibited the problem.
- We built two working privilege escalation exploits that use this effect.
  - Exploiting the DRAM rowhammer bug to gain kernel privileges (Seaborn+, 2015)
- One exploit uses rowhammer-induced bit flips to gain kernel privileges on x86-64 Linux when run as an unprivileged userland process.
- When run on a machine vulnerable to the rowhammer problem, the process was able to induce bit flips in page table entries (PTEs).
- It was able to use this to gain write access to its own page table, and hence gain read-write access to all of physical memory.

### Introducing Half-Double: New hammering technique for DRAM Rowhammer bug

May 25, 2021

Research Team: Salman Qazi, Yoongu Kim, Nicolas Boichat, Eric Shiu & Mattias Nissler

Today, we are sharing details around our discovery of [Half-Double](#), a new Rowhammer technique that capitalizes on the worsening physics of some of the newer DRAM chips to alter the contents of memory.

Rowhammer is a DRAM vulnerability whereby repeated accesses to one address can tamper with the data stored at other addresses. Much like speculative execution vulnerabilities in CPUs, Rowhammer is a breach of the security guarantees made by the underlying hardware. As an electrical coupling phenomenon within the silicon itself, Rowhammer allows the potential bypass of hardware and software memory protection policies. This can allow untrusted code to break out of its sandbox and take full control of the system.

# A Short Retrospective @ 50 Years of ISCA

## Retrospective: Flipping Bits in Memory Without Accessing Them: An Experimental Study of DRAM Disturbance Errors

Onur Mutlu  
ETH Zürich

**Abstract**—Our ISCA 2014 paper [1] provided the first scientific and detailed characterization, analysis, and real-system demonstration of what is now popularly known as the RowHammer phenomenon (or vulnerability) in modern commodity DRAM chips, which are used as main memory in almost all modern computing systems. It experimentally demonstrated that more than 80% of all DRAM modules we tested from the three major DRAM vendors were vulnerable to the RowHammer read disturbance phenomenon; one can predictably induce bitflips (i.e., data corruption) in real DRAM modules by repeatedly accessing a DRAM row and thus causing electrical disturbance to physically nearby rows. We showed that a simple unprivileged user-level program induced RowHammer bitflips in multiple real systems and suggested that a security attack can be built using this proof-of-concept to hijack control of the system or cause other harm. To solve the RowHammer problem, our paper examined seven different approaches (including a novel probabilistic approach that has very low cost), some of which influenced or were adopted in different industrial products.

Many later works from various research communities examined RowHammer, building real security attacks, proposing new defenses, further analyzing the problem at various (e.g., device/circuit, architecture, and system) levels, and exploiting RowHammer for various purposes (e.g., to reverse-engineer DRAM chips). Industry has worked to mitigate the problem, changing both memory controllers and DRAM standards/chips. Two major DRAM vendors finally wrote papers on the topic in 2023, describing their current approaches to mitigate RowHammer. Research & development on RowHammer in both academia & industry continues to be very active and fascinating.

This short retrospective provides a brief analysis of our ISCA 2014 paper and its impact. We describe the circumstances that led to our paper, mention its influence on later works and products, describe the change we believe it has helped enable in hardware security, and discuss our predictions for future.

### I. BACKGROUND AND CIRCUMSTANCES

Our stumbling on the RowHammer problem and creation of its first scientific analysis happened as a result of a confluence of multiple factors. First, my group was working on DRAM technology scaling issues since late 2010. We were very interested in failure mechanisms that appear or worsen due to aggressive technology scaling. To study such issues (e.g., data retention errors [2]), we built an FPGA-based DRAM testing infrastructure [2] between 2011-2012, which we later open sourced as SoTMC [3, 4] and DRAM Bender [5, 6]. Second, around the same timeframe, we were investigating similar technology scaling issues in flash memory using real NAND flash chips [7, 8]. We knew read disturbance errors were significant in NAND flash memory [7–11] and were very interested in how prevalent they were in DRAM. Third, we were collaborating with Intel (e.g., [2]) to understand and solve DRAM technology scaling problems and build our DRAM infrastructure. Three of my students and I spent the summer of 2012 at Intel to work closely with our collaborators (two are co-authors): during this time, we finalized the calibration and stabilization of our infrastructure and had significant technical discussions and experimentation on DRAM scaling problems.

Although there was awareness of the RowHammer problem in industry in 2012 (see Footnote 1 in [1]), there was no comprehensive experimental analysis and detailed real-system demonstration of it. We believed it was critical to provide a rigorous scientific analysis using a wide variety of DRAM chips and scientifically establish major characteristics and prevalence of RowHammer. Hence, in the summer of 2012, we set out to use our DRAM testing infrastructure to analyze RowHammer. Our initial results showed how widespread the read disturbance problem was across the (at the time) recent DRAM chips we tested, so we studied the problem comprehensively and developed many solutions to it. The resulting paper was submitted to MICRO in May 2013 but was rejected. We strengthened the results, especially of the mitigation mechanisms and the number of tested chips, and made the analysis

more comprehensive before it was accepted to ISCA 2014 [2] of the 6 reviewers still rejected it for interesting reasons).

### II. MAJOR CONTRIBUTION AND INFLUENCE

The major contribution of our paper is the exposure and detailed analysis of a fundamental hardware failure mechanism that breaks memory isolation in real systems and thus has huge implications on system reliability, security, and safety. Our paper is a comprehensive study of a major DRAM technology scaling problem, RowHammer, including its first scientific analysis, experimental characterization, real system demonstration, and solutions with their evaluation. To our knowledge, RowHammer is the first example of a hardware failure mechanism that creates a significant and widespread system security vulnerability [12–15], as our ISCA 2014 paper suggested.

Our work has had large influence on both industry & academia. Individual follow-on works are many to list here; we refer the reader to longer invited retrospectives we wrote [12–14]. We give major examples of influence, focusing on RowHammer's effect on the collective mindset of security research and major industry milestones related to RowHammer.

**RowHammer Attacks & Mindset Shift in Hardware Security.** Our demonstration that one can easily and predictably induce bitflips in commodity DRAM chips using a real user-level program enabled a major mindset shift in hardware security. It showed that general-purpose hardware is fallible in a very widespread manner and its problems are exploitable. Tens of works (see [13, 14]) built directly on our work to exploit RowHammer bitflips to develop many attacks that compromise system integrity and confidentiality, starting from the first RowHammer exploit by Google Project Zero in 2015 [16, 17] to recent works in 2022-2023 (e.g., [18, 19]). These attacks showed increasingly sophisticated ways by which an unprivileged attacker can exploit RowHammer bitflips to circumvent memory protection and gain complete control of a system (e.g., [16, 20–28]), gain access to confidential data (e.g., [18, 19, 29]), or maliciously destroy the safety and accuracy of a system, e.g., an otherwise accurate machine learning inference engine (e.g., [30, 31]). The mindset enabled by RowHammer bitflips caused a renewed interest in hardware security research, enticing many researchers to deeply understand hardware's inner workings and find new vulnerabilities. Thus, hardware security issues have become mainstream discussion in top security & architecture venues, some having sessions entitled RowHammer.

**RowHammer Defenses.** Tens of works proposed mitigations against RowHammer, some of which were inspired by the solutions we discussed in our ISCA 2014 paper. To date, the search for more efficient and low-cost RowHammer solutions continues. We refer the reader to our prior overview papers [13, 14, 32] and more recent works in 2023 (e.g., [33–35]).

**RowHammer Analyses.** Our paper initiated works at both architectural & circuit/device-levels to better understand RowHammer and reverse-engineer DRAM chips, to develop better models, defenses, and attacks (see [13, 14]). Our ISCA'20 work [36] revisited RowHammer, comprehensively analyzed of 1580 DRAM chips of three different types from at least two generations, showing that RowHammer has gotten much worse with technology scaling & existing solutions are not effective at future vulnerability levels.

**Industry Reaction: Attacks, Analyses, and Mitigations.** Folks developing industrial memory testing programs immediately included RowHammer tests, e.g., in memtest86 [37], citing our work. Industry needed to immediately protect RowHammer-vulnerable chips already in the field, so almost all system vendors increased refresh rates; a solution we examined in our paper and deemed costly for performance and energy, yet it was the only practical lever that could be used in the field. Apple publicly acknowledged our work in their security release [38] that announced higher refresh rates

to mitigate RowHammer. Intel designed memory controllers that performed probabilistic activations (i.e., pTRR [39, 40]), similar to our PARA solution [1]. DRAM vendors modified the DRAM standard to introduce TRR (target row refresh) mechanisms [39] and claimed their new DDR4 chips to be RowHammer-free [39, 41]. This bold claim was later refuted by our TRRespass work [39] in 2020, which introduced the many-sided RowHammer attack to circumvent internal protection mechanisms added to the DRAM chips. Our later work, Uncovering TRR [41] showed that one can almost completely reverse-engineer and thus easily bypass RowHammer mitigations employed in all tested DRAM chips, i.e., RowHammer solutions in DRAM chips are broken. The industry done by our two major works in 2020 [36, 39] caused the industry to reorganize the RowHammer task group at JEDEC, which produced two white papers on mitigating RowHammer [42, 43]. Nine years after our paper, in 2023, two major DRAM vendors, SK Hynix and Samsung, finally wrote papers [44, 45] on the RowHammer problem, describing their solutions. Several of these industry solutions build on the probabilistic & access-counter-based solution approaches our ISCA 2014 paper introduced.

Major Internet and cloud systems companies also took a deep interest in RowHammer as it can greatly impact their system security, dependability, and availability. Multiple works from Google, e.g., by Google Project Zero in 2015 [16, 17] and Half Double in 2021-2022 [46] directly built on our paper to demonstrate attacks in real systems. Researchers from Microsoft have developed deeper analyses of RowHammer [47], along with new RowHammer attacks [48] and defenses (e.g., [48–51]).

### III. SUMMARY AND FUTURE OUTLOOK

Since 2012-2014, RowHammer vulnerability has become much worse due to technology scaling: without mitigation, one can now induce RowHammer bitflips with orders of magnitude smaller number of activations (e.g., ~10K) and cause much higher rates of errors in cutting-edge DRAM chips [36, 41]. Sophisticated attacks are continuously developed to circumvent the mitigations employed in real DRAM chips. Fortunately, we have also come a long way in further understanding and better mitigating the RowHammer vulnerability. The industry is now (hopefully) fully aware of the importance of the problem and of avoiding bitflips. Unfortunately, an efficient and completely-secure solution is not found yet. The solution space poses a rich area of tradeoffs in terms of security, performance, power/energy, cost/complexity. All solutions forego some desirable properties in favor of others. As such, a critical direction for the future is to find solutions superior to what we have today. We believe system-DRAM cooperation [14, 52] will be important to enabling complete solutions. We also believe it is critical to deeply understand the properties of RowHammer under many different conditions so that we can develop effective solutions that work under all circumstances. Unfortunately, we do not yet fully understand many facets of RowHammer (see [14, 53–55]).

DRAM technology scaling will continue to create problems that will exacerbate the bitflips and the resulting robustness (i.e., safety/security/reliability) problems. Our ISCA 2023 paper on RowPress [55] provides the first scientific and detailed characterization, analysis, and real-system demonstration of yet another read disturbance mechanism in DRAM. What other fascinating problems will we see and can we completely solve them efficiently? Will we ever be free of bitflips at the system and application levels?

\* We report the manufacture date marked on the chip packages, which is more accurate than other dates that can be gleaned from a module.

† We report timing constraints stored in the module's on-board ROM [33], which is read by the system BIOS to calibrate the memory controller.

‡ The maximum DRAM chip size supported by our testing platform is 2Gb.

§ We report DRAM die versions marked on the chip packages, which typically progress in the following manner:  $\mathcal{M} \rightarrow \mathcal{A} \rightarrow \mathcal{B} \rightarrow \mathcal{C} \rightarrow \dots$ .

Table 3. Sample population of 129 DDR3 DRAM modules, categorized by manufacturer and sorted by manufacture date

# RowHammer Characterization Results

1. Most Modules Are at Risk
2. Errors vs. Vintage
3. Error = Charge Loss
4. Adjacency: Aggressor & Victim
5. Sensitivity Studies
6. Other Results in Paper
7. Solution Space

# 4. Adjacency: Aggressor & Victim

*Note: For three modules with the most errors (only first bank)*

*Most aggressors & victims are adjacent*

# 1 Access Interval (Aggressor)

Note: For three modules with the most errors (only first bank)

*Less frequent accesses  $\rightarrow$  Fewer errors*

## 2 Refresh Interval

*Note: Using three modules with the most errors (only first bank)*

*More frequent refreshes  $\rightarrow$  Fewer errors*

### 3 Data Pattern

10x Errors

*Errors affected by data stored in other cells*

# 6. Other Key Observations [ISCA'14]

- *Victim Cells  $\neq$  Retention-Weak Cells*
  - Almost no overlap between them
- *Errors are repeatable*
  - Across ten iterations of testing, >70% of victim cells had errors in every iteration
- *As many as 4 errors per cache-line*
  - Simple ECC (e.g., SECDED) cannot prevent all errors
- *Cells affected by two aggressors on either side*
  - Double sided hammering

# RowHammer Solutions

# Two Types of RowHammer Solutions

---

## ■ Immediate

- ❑ To protect the vulnerable DRAM chips in the field
- ❑ Limited possibilities

## ■ Longer-term

- ❑ To protect future DRAM chips
- ❑ Wider range of protection mechanisms

## ■ Our ISCA 2014 paper proposes both types of solutions

- ❑ Seven solutions in total
- ❑ PARA proposed as best solution → already employed in the field

# RowHammer Solution Approaches

- More robust DRAM chips **and/or** error-correcting codes
- Increased refresh rate

- Physical isolation

Cost, Power, Performance, Complexity

- Reactive refresh

- Proactive throttling

SAFARI

Fewer activations allowed for aggressive applications

# Apple's Security Patch for RowHammer

---

- <https://support.apple.com/en-gb/HT204934>

Available for: OS X Mountain Lion v10.8.5, OS X Mavericks v10.9.5

Impact: A malicious application may induce memory corruption to escalate privileges

Description: A disturbance error, also known as Rowhammer, exists with some DDR3 RAM that could have led to memory corruption. This issue was mitigated by increasing memory refresh rates.

CVE-ID

CVE-2015-3693 : Mark Seaborn and Thomas Dullien of Google, working from original research by Yoongu Kim et al (2014)

HP, Lenovo, and many other vendors released similar patches

---

# Our First Solution to RowHammer

- *PARA: Probabilistic Adjacent Row Activation*
- Key Idea
  - After closing a row, activate (i.e., refresh) its neighbors with a low probability:  $p = 0.005$
- Reliability Guarantee
  - When  $p=0.005$ , errors in one year:  $9.4 \times 10^{-14}$
  - By adjusting the value of  $p$ , we can vary the strength of protection against errors

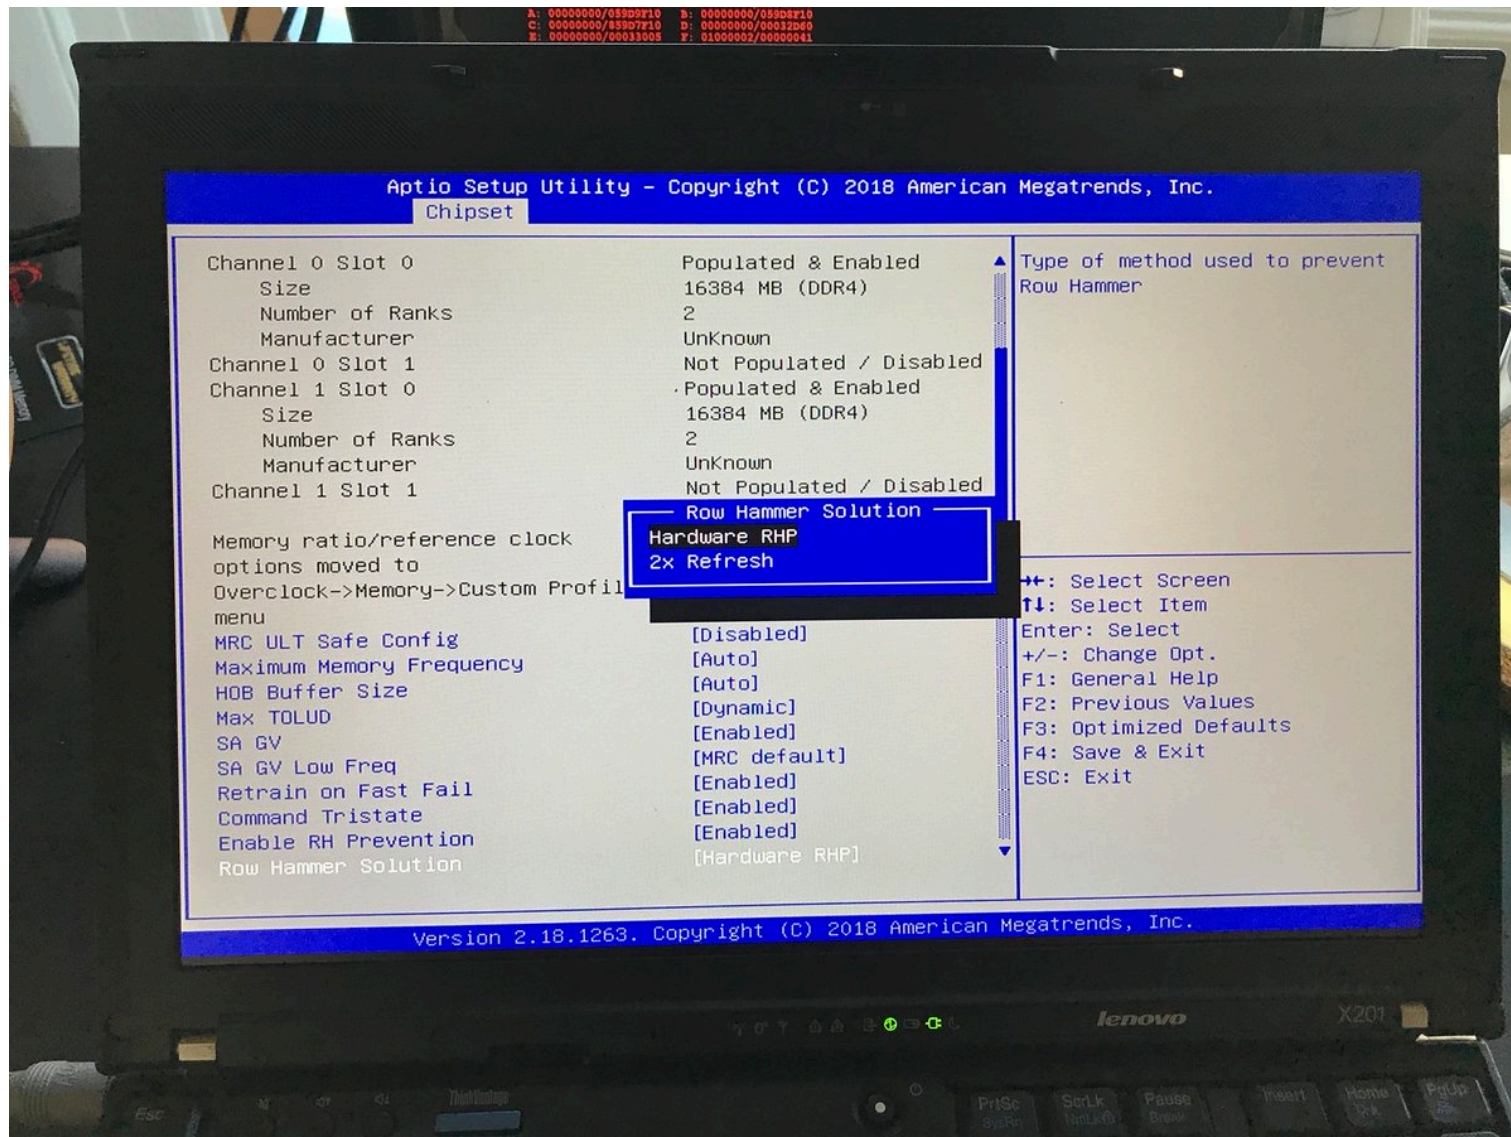

# Advantages of PARA

- *PARA refreshes rows infrequently*
  - Low power
  - Low performance-overhead
    - Average slowdown: **0.20%** (for 29 benchmarks)
    - Maximum slowdown: **0.75%**
- *PARA is stateless*
  - Low cost
  - Low complexity
- *PARA is an effective and low-overhead solution to prevent disturbance errors*

# Requirements for PARA

- If implemented in **DRAM chip** (done today)
  - Enough slack in timing and refresh parameters
  - Plenty of slack today:
    - Lee et al., “**Adaptive-Latency DRAM: Optimizing DRAM Timing for the Common Case**,” HPCA 2015.
    - Chang et al., “**Understanding Latency Variation in Modern DRAM Chips**,” SIGMETRICS 2016.
    - Lee et al., “**Design-Induced Latency Variation in Modern DRAM Chips**,” SIGMETRICS 2017.

    - Kim et al., “**Solar-DRAM: Reducing DRAM Access Latency by Exploiting the Variation in Local Bitlines**,” ICCD 2018.
- If implemented in **memory controller**
  - Need coordination between controller and DRAM
  - Memory controller should know which rows are physically adjacent

# Two Major RowHammer Directions

---

## ■ **Understanding RowHammer**

- Many effects still need to be rigorously examined
  - Aging of DRAM Chips
  - Environmental Conditions (e.g., Process, Voltage, Temperature)
  - Memory Access Patterns
  - Memory Controller & System Design Decisions
  - ...

## ■ **Solving RowHammer**

- Flexible and efficient solutions are necessary
  - In-field patchable / reconfigurable / programmable solutions
- Co-architecting System and Memory is important
  - To avoid performance and denial-of-service problems

# RowHammer in 2020-2024

## Revisiting RowHammer: An Experimental Analysis of Modern DRAM Devices and Mitigation Techniques

Jeremie S. Kim<sup>§†</sup>      Minesh Patel<sup>§</sup>      A. Giray Yağlıkçı<sup>§</sup>  
Hasan Hassan<sup>§</sup>      Roknoddin Azizi<sup>§</sup>      Lois Orosa<sup>§</sup>      Onur Mutlu<sup>§†</sup>  
<sup>§</sup>*ETH Zürich*      <sup>†</sup>*Carnegie Mellon University*

# Key Takeaways from 1580 Chips

- **Newer DRAM chips are much more vulnerable to RowHammer (more bit flips, happening earlier)**
- There are new chips whose weakest cells fail after **only 4800 hammers**
- Chips of newer DRAM technology nodes can exhibit RowHammer bit flips 1) in **more rows** and 2) **farther away** from the victim row.
- **Existing mitigation mechanisms are NOT effective at future technology nodes**

# 1580 DRAM Chips Tested

DRAM type-node	Number of Chips (Modules) Tested			
	Mfr. A	Mfr. B	Mfr. C	Total
DDR3-old	56 (10)	88 (11)	28 (7)	172 (28)
DDR3-new	80 (10)	52 (9)	104 (13)	236 (32)
DDR4-old	112 (16)	24 (3)	128 (18)	264 (37)
DDR4-new	264 (43)	16 (2)	108 (28)	388 (73)
LPDDR4-1x	12 (3)	180 (45)	N/A	192 (48)
LPDDR4-1y	184 (46)	N/A	144 (36)	328 (82)

**1580** total DRAM chips tested from **300** DRAM modules

- **Three** major DRAM manufacturers {A, B, C}
- **Three** DRAM *types or standards* {DDR3, DDR4, LPDDR4}
  - LPDDR4 chips we test implement on-die ECC
- **Two** technology nodes per DRAM type {old/new, 1x/1y}
  - Categorized based on manufacturing date, datasheet publication date, purchase date, and characterization results

**Type-node:** configuration describing a chip's type and technology node generation: **DDR3-old/new, DDR4-old/new, LPDDR4-1x/1y**

# 3. Hammer Count (HC) Effects

RowHammer bit flip rates **increase**  
when going **from old to new** DDR4 technology node generations

**RowHammer bit flip rates (i.e., RowHammer vulnerability)  
increase with technology node generation**

# Mitigation Mechanism Evaluation

**Ideal** mechanism is **significantly better** than any existing mechanism for  $HC_{first} < 1024$

**Significant opportunity** for developing a RowHammer solution with **low performance overhead** that supports low  $HC_{first}$

RowHammer is a  
technology scaling problem

Finding a good solution to  
RowHammer is difficult  
(and will become more so)

# Reported $HC_{\text{first}}$ Values (2012 – Now)

\*Not shown: Significant variance in  $HC_{\text{first}}$  across vendors and die variations

# New RowHammer Characteristics

# RowHammer Has Many Dimensions

# Our Goal

Provide insights into **three fundamental properties**

Temperature

Aggressor Row  
Active Time

Victim DRAM Cell's  
Physical Location

To find **effective and efficient** attacks and defenses

# Summary of The Study & Key Results

- **272 DRAM chips** from **four major manufacturers**
- **6 major takeaways** from **16 novel observations**
- A RowHammer bit flip is **more likely to occur**
  - 1) in a **bounded range of temperature**
  - 2) if the aggressor row is **active for longer time**
  - 3) in **certain physical regions** of the DRAM module under attack
- Our novel observations can inspire and aid future work
  - Craft **more effective attacks**
  - Design **more effective and efficient defenses**

# Example Attack Improvement 3: Bypassing Defenses with Aggressor Row Active Time

Activating aggressor rows as frequently as possible:

Keeping aggressor rows active for a longer time:

**Reduces** the minimum activation count to induce a bit flip **by 36%**

**Bypasses defenses** that do not account for this reduction

# Example Defense Improvements

- **Example 1: Leveraging variation across DRAM rows**

- **Example 2: Leveraging variation with temperature**

- A DRAM cell experiences **bit flips** within a **bounded temperature range**

- A row can be **disabled** within the row's **vulnerable temperature range**

# Deeper Look into RowHammer: Talk Video

**Our Goal**

Provide insights into **three fundamental properties**

Temperature

Aggressor Row  
Active Time

Victim DRAM Cell's  
Physical Location

To find **effective and efficient** attacks and defenses

# Updated DRAM Testing Infrastructure

FPGA-based SoftMC (Xilinx Virtex UltraScale+ XCU200)

Fine-grained control over DRAM commands,  
timing parameters ( $\pm 1.5\text{ns}$ ), temperature ( $\pm 0.1^\circ\text{C}$ ),  
and wordline voltage ( $\pm 1\text{mV}$ )

# Summary

We provide *the first* RowHammer characterization **under reduced wordline voltage**

Experimental results with 272 *real DRAM chips* show that **reducing wordline voltage**:

## 1. Reduces RowHammer vulnerability

- **Bit error rate** caused by a RowHammer attack reduces by **15.2% (66.9% max)**
- A row needs to be activated **7.4% more times (85.8% max)** to induce *the first* bit flip

## 2. Increases row activation latency

- More than **76%** of the tested DRAM chips **reliably operate** using **nominal** timing parameters
- Remaining **24%** **reliably operate** with **increased** (up to 24ns) row activation latency

## 3. Reduces data retention time

- **80%** of the tested DRAM chips **reliably operate using nominal refresh rate**
- Remaining **20%** **reliably operate** by
  - Using **single error correcting codes**
  - **Doubling the refresh rate** for **a small fraction (16.4%) of DRAM rows**

Reducing wordline voltage can **reduce RowHammer vulnerability**  
*without* significantly affecting **reliable DRAM operation**

# RowHammer vs. Wordline Voltage: Talk Video

## Our Hypothesis

Reducing **wordline voltage**  
can **reduce RowHammer vulnerability**  
*without* significantly affecting **reliable DRAM operation**

# A Poor RowHammer Solution

---

# TRRespass

---

- First work to show that TRR-protected DRAM chips are vulnerable to RowHammer in the field
  - Mitigations advertised as secure are not secure
- Introduces the Many-sided RowHammer attack
  - Idea: Hammer many rows to bypass TRR mitigations (e.g., by overflowing proprietary TRR tables that detect aggressor rows)
- (Partially) reverse-engineers the TRR and pTRR mitigation mechanisms implemented in DRAM chips and memory controllers
- Provides an automatic tool that can effectively create many-sided RowHammer attacks in DDR4 and LPDDR4(X) chips

# Example Many-Sided Hammering Patterns

(a) Assisted double-sided

(b) 4-sided

**Fig. 12:** Hammering patterns discovered by *TRRespass*. Aggressor rows are in red (■) and victim rows are in blue (■).

# BitFlips vs. Number of Aggressor Rows

**Fig. 10: Bit flips vs. number of aggressor rows.** Module  $C_{12}$ : Number of bit flips in bank 0 as we vary the number of aggressor rows. Using SoftMC, we refresh DRAM with standard  $t_{REFI}$  and run the tests until each aggressor rows is hammered 500K times.

**Fig. 11: Bit flips vs. number of aggressor rows.** Module  $A_{15}$ : Number of bit flips in bank 0 as we vary the number of aggressor rows. Using SoftMC, we refresh DRAM with standard  $t_{REFI}$  and run the tests until each aggressor rows is hammered 500K times.

**Fig. 13: Bit flips vs. number of aggressor rows.** Module  $A_{10}$ : Number of bit flips triggered with  $N$ -sided RowHammer for varying number of  $N$  on Intel Core i7-7700K. Each aggressor row is one row away from the closest aggressor row (i.e., VAVAVA... configuration) and aggressor rows are hammered in a round-robin fashion.

# TRRespass Vulnerable DRAM Modules

TABLE II: *TRRespass* results. We report the number of patterns found and bit flips detected for the 42 DRAM modules in our set.

Module	Date (yy-ww)	Freq. (MHz)	Size (GB)	Organization			MAC	Found Patterns	Best Pattern	Corruptions			Double Refresh

# TRRespass Based RowHammer Attack

**TABLE IV: Time to exploit.** Time to find the first exploitable template on two sample modules from each DRAM vendor.

<i>Module</i>	$\tau$ (ms)	<i>PTE</i> [81]	<i>RSA-2048</i> [79]	<i>sudo</i> [27]
$\mathcal{A}_{14}$	188.7	4.9s	6m 27s	—
$\mathcal{A}_4$	180.8	38.8s	39m 28s	—
$\mathcal{B}_1$	360.7	—	—	—
$\mathcal{B}_2$	331.2	—	—	—
$\mathcal{C}_{12}$	300.0	2.3s	74.6s	54m16s
$\mathcal{C}_{13}$	180.9	3h 15m	—	—

$\tau$ : Time to template a single row: time to fill the victim and aggressor rows + hammer time + time to scan the row.

# TRRespass Key Results

---

- 13 out of 42 tested DDR4 DRAM modules are vulnerable
  - From all 3 major manufacturers
  - 3-, 9-, 10-, 14-, 19-sided hammer attacks needed
- 5 out of 13 mobile phones tested vulnerable
  - From 4 major manufacturers
  - With LPDDR4(X) DRAM chips
- These results are scratching the surface
  - TRRespass tool is not exhaustive
  - There is a lot of room for uncovering more vulnerable chips and phones

RowHammer is still  
an open problem

Security by obscurity  
is likely not a good solution

# Improvements in JEDEC (2020-2021)

## NEAR-TERM DRAM LEVEL ROWHAMMER MITIGATION

### JEP300-1

Published: Mar 2021

RAM process node transistor scaling for power and DRAM capacity has made DRAM cells more sensitive to disturbances or transient faults. This sensitivity becomes much worse if external stresses are applied in a meticulously manipulated sequence, such as Rowhammer. Rowhammer related papers have been written outside of JEDEC, but some assumptions used in those papers didn't explain the problem very clearly or correctly, so the perception for this matter is not precisely understood within the industry. This publication defines the problem and recommends following mitigations to address such concerns across the DRAM industry or academia. Item 1866.01.

Committee(s): [JC-42](#)

<https://www.jedec.org/standards-documents/docs/jep300-1>

## SYSTEM LEVEL ROWHAMMER MITIGATION

### JEP301-1

Published: Mar 2021

A DRAM rowhammer security exploit is a serious threat to cloud service providers, data centers, laptops, smart phones, self-driving cars and IoT devices. Hardware research and development will take time. DRAM components, DRAM DIMMs, System-on-chip (SoC), chipsets and system products have their own design cycle time and overall life time. This publication recommends best practices to mitigate the security risks from rowhammer attacks. Item 1866.02.

### Introducing Half-Double: New hammering technique for DRAM Rowhammer bug

May 25, 2021

Research Team: Salman Qazi, Yoongu Kim, Nicolas Boichat, Eric Shiu & Mattias Nissler

Today, we are sharing details around our discovery of [Half-Double](#), a new Rowhammer technique that capitalizes on the worsening physics of some of the newer DRAM chips to alter the contents of memory.

Rowhammer is a DRAM vulnerability whereby repeated accesses to one address can tamper with the data stored at other addresses. Much like speculative execution vulnerabilities in CPUs, Rowhammer is a breach of the security guarantees made by the underlying hardware. As an electrical coupling phenomenon within the silicon itself, Rowhammer allows the potential bypass of hardware and software memory protection policies. This can allow untrusted code to break out of its sandbox and take full control of the system.

# Google's Half-Double RowHammer Attack (May 2021)

- Given three consecutive rows A, B, and C, we were able to attack C by directing a very large number of accesses to A, along with just a handful (~dozens) to B.
- Based on our experiments, accesses to B have a non-linear gating effect, in which they appear to “transport” the Rowhammer effect of A onto C.
- This is likely an indication that the electrical coupling responsible for **Rowhammer** is a property of distance, **effectively becoming stronger** and longer-ranged as cell geometries shrink down.

### ABSTRACT

Prior work shows that Rowhammer attacks—which flip bits in DRAM via frequent activations of the same row(s)—are viable. Adversaries typically mount these attacks via instruction sequences that are carefully-crafted to bypass CPU caches. However, we discover a novel form of hammering that we refer to as *coherence-induced hammering*, caused by Intel's implementations of cache coherent non-uniform memory access (ccNUMA) protocols. We show that this hammering *occurs in commodity benchmarks* on a major cloud provider's production hardware, the first hammering found to be generated by non-malicious code. Given DRAM's rising susceptibility to bit flips, it is paramount to prevent coherence-induced hammering to ensure reliability and security in the cloud.

### 1 INTRODUCTION

The threat of Rowhammer [61] bit flips (i.e., DRAM disturbances) is a widespread concern, especially in multi-tenant computing environments such as the cloud. Rowhammer arises from frequent activations—to a first approximation, accesses—of the same DRAM rows, which can disturb data in nearby rows due to electromagnetic interference. These bit flips manifest at the system level as data loss, machine failure, or system subversion.

Prior attacks and analyses [20, 22, 25, 30, 38, 39, 41, 48, 49, 51, 58, 61, 65, 70, 84, 88, 94, 95, 101, 108, 111–114, 119] confirm that malicious adversaries can trigger sufficient activations to flip bits, establishing Rowhammer as a *security* threat. At a high level, existing attacks require a carefully-crafted sequence of instructions to

# Two Key Challenges

1

## **Scalability**

with worsening RowHammer vulnerability

2

## **Compatibility**

with commodity DRAM chips

# BlockHammer: Practical Throttling-based Mechanism

- A RowHammer attack hammers Row A
- **BlockHammer** detects a RowHammer attack using **area-efficient Bloom filters**
- **BlockHammer** **selectively throttles** accesses from within **the memory controller**
- Bit flips **do not** occur
- BlockHammer can *optionally* **inform the system software** about the attack

Physical  
Row Layout

**BlockHammer** is **compatible with commodity DRAM chips**  
**No need** for **proprietary info** of or **modifications** to DRAM chips

**Main Memory Needs**  
**Intelligent Controllers**  
**for Security, Safety,**  
**Reliability, Scaling**

# RowHammer Solution Approaches

- More robust DRAM chips **and/or** error-correcting codes
- Increased refresh rate

- Physical isolation

- Reactive refresh

- Proactive throttling

**SAFARI**

Fewer activations allowed for aggressive applications

# Industry's RowHammer Solutions (I)

---

SK hynix Semiconductor, Icheon, Korea

DRAM products have been recently adopted in a wide range of high-performance computing applications: such as in cloud computing, in big data systems, and IoT devices. This demand creates larger memory capacity requirements, thereby requiring aggressive DRAM technology node scaling to reduce the cost per bit [1,2]. However, DRAM manufacturers are facing technology scaling challenges due to row hammer and refresh retention time beyond 1a-nm [2]. Row hammer is a failure mechanism, where repeatedly activating a DRAM row disturbs data in adjacent rows. Scaling down severely threatens reliability since a reduction of DRAM cell size leads to a reduction in the intrinsic row hammer tolerance [2,3]. To improve row hammer tolerance, there is a need to probabilistically activate adjacent rows with carefully sampled active addresses and to improve intrinsic row hammer tolerance [2]. In this paper, row-hammer-protection and refresh-management schemes are presented to guarantee DRAM security and reliability despite the aggressive scaling from 1a-nm to sub 10-nm nodes. The probabilistic-aggressor-tracking scheme with a refresh-management function (RFM) and per-row hammer tracking (PRHT) improve DRAM resilience. A multi-step precharge reinforces intrinsic row-hammer tolerance and a core-bias modulation improves retention time: even in the face of cell-transistor degradation due to technology scaling. This comprehensive scheme leads to a reduced probability of failure, due to row hammer attacks, by 93.1% and an improvement in retention time by 17%.

Version 1.30

This standard defines the DDR5 SDRAM specification, including features, functionalities, AC and DC characteristics, packages, and ball/signal assignments. The purpose of this Standard is to define the minimum set of requirements for JEDEC compliant 8 Gb through 32 Gb for x4, x8, and x16 DDR5 SDRAM devices. This standard was created based on the DDR4 standards (JESD79-4) and some aspects of the DDR, DDR2, DDR3, and LPDDR4 standards (JESD79, JESD79-2, JESD79-3, and JESD209-4).

# High-Level Summary

- We demonstrate and analyze **RowPress, a new read disturbance phenomenon** that causes bitflips in real DRAM chips
- We show that RowPress is **different from the RowHammer vulnerability**
- We demonstrate RowPress **using a user-level program** on a real Intel system with real DRAM chips
- We provide **effective solutions** to RowPress

# What is RowPress?

Keeping a DRAM row **open for a long time** causes bitflips in adjacent rows

These bitflips do **NOT** require many row activations

**Only one activation** is enough in some cases!

Now, let's delve into some background and see how this is **different from RowHammer**

# Are There Other Read-Disturb Issues in DRAM?

- RowHammer is the only studied read-disturb phenomenon
- Mitigations work by detecting **high row activation count**

What if there is another read-disturb phenomenon that **does NOT rely on high row activation count**?

[https://www.reddit.com/r/CrappyDesign/comments/arw0q8/now\\_this\\_this\\_is\\_poor\\_fencing/](https://www.reddit.com/r/CrappyDesign/comments/arw0q8/now_this_this_is_poor_fencing/)

# RowPress vs. RowHammer

Instead of using a high activation count,

☞ increase the time that the aggressor row stays open

**RowHammer**  
**Aggressor Row**

**RowPress**  
**Aggressor Row**

We observe bitflips even with **ONLY ONE activation** in extreme cases where the row stays open for 30ms

# Real DRAM Chip Characterization (I)

## FPGA-Based DDR4 Testing Infrastructure

- Based on [SoftMC \[Hassan+, HPCA'17\]](#) and [DRAM Bender \[Olgun+, TCAD'23\]](#)
- **Fine-grained control** over DRAM commands, timings, and temperature

# Real DRAM Chip Characterization (II)

## DRAM chips tested

- 164 DDR4 chips from all 3 major DRAM manufacturers
- Covers different die densities and revisions

Mfr.	#DIMMs	#Chips	Density	Die Rev.	Org.	Date
Mfr. S (Samsung)	2	8	8Gb	B	x8	20-53
	1	8	8Gb	C	x8	N/A
	3	8	8Gb	D	x8	21-10

	2	4	16Gb	B	x16	21-26
	1	16	16Gb	E	x4	20-14
	2	4	16Gb	E	x16	20-46
	1	4	16Gb	F	x16	21-50

# Major Takeaways from Real DRAM Chips

RowPress significantly **amplifies** DRAM's vulnerability to **read disturbance**

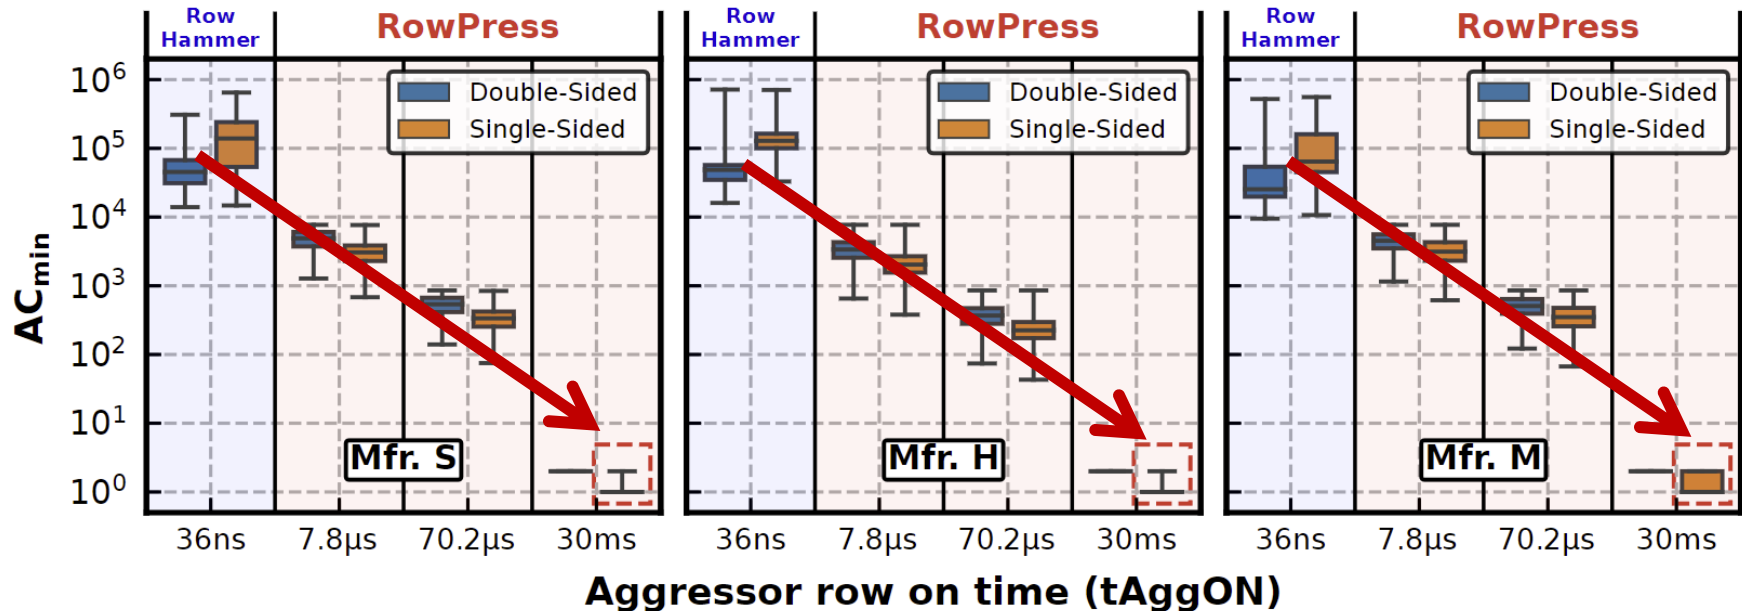

RowPress has a **different** underlying error **mechanism** from RowHammer

# Key Characteristics of RowPress (I)

## Amplifying Read Disturbance in DRAM

- Reduces the minimum number of row activations needed to induce a bitflip ( $AC_{min}$ ) by **1-2 orders of magnitude**
- In extreme cases, activating a row **only once** induces bitflips

# RowPress at $t_{\text{AggON}} = \text{Refresh Interval}$

\*Not shown: Significant variance in  $\text{HC}_{\text{first}}$  across vendors and die variations

# RowPress at $t_{\text{AggON}} = 9 * \text{Refresh Interval}$

$\text{HC}_{\text{first}} = \infty$   
(all good)

$\text{HC}_{\text{first}} \text{ Scale}^*$

$\text{HC}_{\text{first}} = 1$   
(DRAM is doomed)

*row on time = 70.2 us*  
DDR4-new @ **51**  
[Luo+, ISCA'23]

*row on time = 35.1 us*  
HBM2-20nm @ **123**  
[Olgun+, DSN'24]

\*Not shown: Significant variance in  $\text{HC}_{\text{first}}$  across vendors and die variations

# Key Characteristics of RowPress (II)

## Amplifying Read Disturbance in DRAM

- Reduces the minimum number of row activations needed to induce a bitflip ( $AC_{min}$ ) by **1-2 orders of magnitude**
- In extreme cases, activating a row **only once** induces bitflips
- Gets worse as **temperature increases**

## Different From RowHammer

- Affects a **different set of cells** compared to RowHammer and retention failures
- **Behaves differently** as access pattern and temperature changes compared to RowHammer

# Real-System Demonstration (I)

Intel Core i5-10400  
(Comet Lake)

Samsung DDR4 Module  
M378A2K43CB1-CTD  
(Date Code: 20-10)  
w/ TRR RowHammer Mitigation

**Key Idea:** A proof-of-concept RowPress program keeps a DRAM row open for a longer period by **keeping on accessing different cache blocks in the row**

```
// Sync with Refresh and Loop Below
```

```
for (k = 0; k < NUM_AGGR_ACTS; k++)  
    for (j = 0; j < NUM_READS; j++) *AGGRESSOR1[j];  
    for (j = 0; j < NUM_READS; j++) *AGGRESSOR2[j];  
    for (j = 0; j < NUM_READS; j++)  
        clflushopt(AGGRESSOR1[j]);  
        clflushopt(AGGRESSOR2[j]);  
    mfence();  
    activate_dummy_rows();
```

**Number of Cache Blocks Accessed  
Per Aggressor Row ACT  
(NUM\_READS=1 is Rowhammer)**

# Real-System Demonstration (II)

On 1500 victim rows

**Leveraging RowPress, our user-level program induces bitflips when RowHammer cannot**

# Mitigating RowPress (I)

We propose a methodology to adapt existing RowHammer mitigations to **also mitigate RowPress**

## Key Idea:

1. Limit the maximum row open time (**tmro**)
2. Configure the RowHammer mitigation to account for the **RowPress-induced reduction in ACmin**

# Mitigating RowPress (II)

## Key evaluation results

**Additional Performance Overhead of Graphene-RP**

**Additional Performance Overhead of PARA-RP**

**Our solutions mitigate RowPress  
at low additional performance overhead**

# More Results & Source Code

## Many more results & analyses in the paper

- 6 major takeaways
- 19 major empirical observations
- 3 more potential mitigations

More to Come...

# Two Major Directions

---

- **Understanding Bitflips (Hardware errors in general)**
  - Many effects on bitflips still need to be rigorously examined
    - Aging of DRAM Chips
    - Environmental Conditions (e.g., Process, Voltage, Temperature)
    - Memory Access Patterns
    - Memory Controller & System Design Decisions
    - ...
  
- **Solving Bitflips (Hardware errors in general)**
  - Flexible and efficient solutions are necessary
    - In-field patchable / reconfigurable / programmable solutions
  - Co-architecting across the system stack/components is important
    - To avoid performance and denial-of-service problems

# Self-Managing DRAM: Overview

## Self-Managing DRAM (SMD)

enables autonomous in-DRAM maintenance operations

### Key Idea:

Prevent the memory controller from accessing DRAM regions that are *under maintenance* by **rejecting** row activation (**ACT**) commands

Leveraging the ability to *reject an ACT*, a **maintenance operation** can be implemented **completely within a DRAM chip**

# SMD-Based Maintenance Mechanisms

## DRAM Refresh

### Fixed Rate (SMD-FR)

*uniformly* refreshes **all** DRAM rows with a **fixed** refresh period

### Variable Rate (SMD-VR)

*skips* refreshing rows that can **retain their data for longer** than the default refresh period

## RowHammer Protection

### Probabilistic (SMD-PRP)

Performs **neighbor** row refresh with a **small probability** on every row activation

### Deterministic (SMD-DRP)

*keeps track* of most **frequently activated** rows and performs **neighbor** row refresh when activation count threshold is exceeded

## Memory Scrubbing

### Periodic Scrubbing (SMD-MS)

periodically **scans** the **entire** DRAM for errors and corrects them

# Self-Managing DRAM: Summary

The three major DRAM maintenance operations:

- ❖ Refresh
- ❖ RowHammer Protection
- ❖ Memory Scrubbing

Implementing new **maintenance mechanisms** often requires **difficult-to-realize changes**

## Our Goal

- ① Ease the process of enabling new DRAM maintenance operations
- ② Enable more efficient in-DRAM maintenance operations

## Self-Managing DRAM (SMD)

Enables implementing new **in-DRAM** maintenance mechanisms with **no further changes** in the *DRAM interface* and *memory controller*

SMD-based *refresh*, *RowHammer protection*, and *scrubbing* achieve **9.2% speedup** and **6.2% lower DRAM energy** vs. conventional DRAM

# Talk on Self-Managing DRAM

## Problem: The Rigid DRAM Interface

The **Memory Controller** manages DRAM maintenance operations

Changes to maintenance operations are often reflected to the memory controller design, DRAM interface, and other system components

Implementing new maintenance operations  
(or modifying the existing ones) is difficult-to-realize

### ***Six Years of Rowhammer: Breakthroughs and Future Directions***

Stefan Saroiu

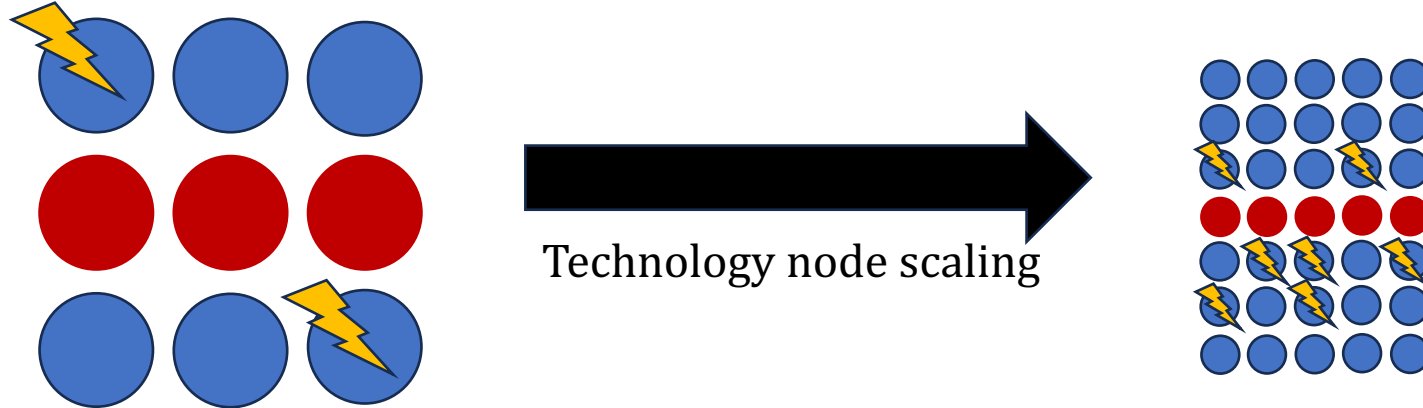

Microsoft Research

This talk will present the work done over the past six years as part of Project STEMA at Microsoft. STEMA stands for Secure, Trusted, and Enhanced Memory for Azure. We will discuss our journey in understanding Rowhammer, developing a testing methodology for cloud providers, and finding effective solutions for the DRAM industry to address Rowhammer once and for all. We will also highlight significant related work that has helped keep the DRAM industry honest. We will explain why Rowhammer remains a significant attack vector, particularly in the context of nation-state attacks, and how this has driven us to develop a suite of pragmatic solutions. Finally, we will argue that Rowhammer is far from being a solved problem and outline several important research challenges that remain in this space.

# Future Memory Robustness Challenges

# Technology Scaling Worsens Vulnerability

DRAM cells become **increasingly more vulnerable (to read disturbance)**

# Future of Main Memory Robustness

---

- DRAM is becoming less reliable → more vulnerable
- Due to difficulties in DRAM scaling, other problems may also appear (or they may be going unnoticed)
- Some errors may already be slipping into the field
  - Read disturb errors (Rowhammer)
  - Retention errors
  - Read errors, write errors
  - ...
- These errors can also pose security vulnerabilities

# Future of Main Memory Robustness

---

- DRAM
- Flash memory
- Emerging Technologies
  - Phase Change Memory
  - STT-MRAM
  - RRAM, memristors
  - ...

# Architecting Robust Memory Systems

---

- **Understand:** Methods for vulnerability modeling & discovery
  - Modeling and prediction based on real (device) data and analysis
- **Architect:** Principled architectures with security as key concern
  - Good partitioning of duties across the stack
  - Cannot give up performance and efficiency
  - Patch-ability in the field
- **Design & Test:** Principled design, automation, (online) testing
  - Design for security/safety/reliability
  - High coverage and good interaction with system reliability methods

# Understand and Model with Experiments (DRAM)

# Understand and Model with Experiments (DRAM)

## Five out of the box FPGA-based prototypes

# Understand and Model with Experiments (Flash)

## Intelligent Memory Controllers

Can Avoid Such Failures

**Main Memory Needs**  
**Intelligent Controllers**  
**for Security, Safety,**  
**Reliability, Scaling**

# Fundamentally Robust (Reliable, Secure, Safe) Computing Architectures

# Final Thoughts on RowHammer

# Aside: Byzantine Failures

---

- This class of failures is known as **Byzantine failures**
- Characterized by
  - **Undetected erroneous computation**
  - Opposite of “fail fast (with an error or no result)”
- “erroneous” can be “malicious” (intent is the only distinction)
- Very difficult to detect and confine Byzantine failures
- **Do all you can to avoid them**
- Lamport et al., “The Byzantine Generals Problem,” ACM TOPLAS 1982.

# Aside: Byzantine Generals Problem

---

## The Byzantine Generals Problem

LESLIE LAMPORT, ROBERT SHOSTAK, and MARSHALL PEASE  
SRI International

---

Reliable computer systems must handle malfunctioning components that give conflicting information to different parts of the system. This situation can be expressed abstractly in terms of a group of generals of the Byzantine army camped with their troops around an enemy city. Communicating only by messenger, the generals must agree upon a common battle plan. However, one or more of them may be traitors who will try to confuse the others. The problem is to find an algorithm to ensure that the loyal generals will reach agreement. It is shown that, using only oral messages, this problem is solvable if and only if more than two-thirds of the generals are loyal; so a single traitor can confound two loyal generals. With unforgeable written messages, the problem is solvable for any number of generals and possible traitors. Applications of the solutions to reliable computer systems are then discussed.

Categories and Subject Descriptors: C.2.4. [**Computer-Communication Networks**]: Distributed Systems—*network operating systems*; D.4.4 [**Operating Systems**]: Communications Management—*network communication*; D.4.5 [**Operating Systems**]: Reliability—*fault tolerance*

General Terms: Algorithms, Reliability

Additional Key Words and Phrases: Interactive consistency

## Using Memory Errors to Attack a Virtual Machine

Sudhakar Govindavajhala \*      Andrew W. Appel  
Princeton University  
{sudhakar,appel}@cs.princeton.edu

*We present an experimental study showing that soft memory errors can lead to serious security vulnerabilities in Java and .NET virtual machines, or in any system that relies on type-checking of untrusted programs as a protection mechanism. Our attack works by sending to the JVM a Java program that is designed so that almost any memory error in its address space will allow it to take control of the JVM. All conventional Java and .NET virtual machines are vulnerable to this attack. The technique of the attack is broadly applicable against other language-based security schemes such as proof-carrying code.*

*We measured the attack on two commercial Java Virtual Machines: Sun's and IBM's. We show that a single-bit error in the Java program's data space can be exploited to execute arbitrary code with a probability of about 70%, and multiple-bit errors with a lower probability.*

*Our attack is particularly relevant against smart cards or tamper-resistant computers, where the user has physical access (to the outside of the computer) and can use various means to induce faults; we have successfully used heat. Fortunately, there are some straightforward defenses against this attack.*

### 7 Physical fault injection

If the attacker has physical access to the outside of the machine, as in the case of a smart card or other tamper-resistant computer, the attacker can induce memory errors. We considered attacks on boxes in form factors ranging from a credit card to a palmtop to a desktop PC.

We considered several ways in which the attacker could induce errors.<sup>4</sup>

SON OF ROWHAMMER —

## There's a new way to flip bits in DRAM, and it works against the latest defenses

New technique produces lots of bitflips and could one day help form an attack.

DAN GOODIN - 10/19/2023, 5:30 AM

# RowHammer: Retrospective

---

- New mindset that has enabled a renewed interest in HW security attack research:
  - ❑ Real (memory) chips are vulnerable, in a simple and widespread manner  
→ this causes real security problems
  - ❑ Hardware reliability → security connection is now mainstream discourse
- Many new RowHammer & bitflip attacks...
  - ❑ Tens of papers in top security, architecture, systems venues
  - ❑ **More to come** as RowHammer is getting worse (DDR4 & beyond)
- Many new RowHammer solutions...
  - ❑ Apple security release; Memtest86 updated
  - ❑ Many solution proposals in top venues (latest in HPCA/Usenix Sec 2024)
  - ❑ Principled system-DRAM co-design (in original RowHammer paper)
  - ❑ **More to come...**

# Perhaps Most Importantly...

---

- RowHammer enabled a shift of mindset in mainstream security researchers
  - General-purpose hardware is fallible, in a widespread manner
  - Its problems are exploitable
- This mindset has enabled many systems security researchers to examine hardware in more depth
  - And understand HW's inner workings and vulnerabilities
- It is no coincidence that two of the groups that discovered Meltdown and Spectre heavily worked on RowHammer attacks before
  - **More to come...**

# Conclusion

# Summary: RowHammer

---

- Memory reliability is reducing
- Reliability issues open up security and safety vulnerabilities
  - Very hard to defend against
- **Rowhammer is a prime example**
  - First example of how a simple hardware failure mechanism can create a widespread system security vulnerability
  - Implications on system security & safety are tremendous & exciting
- Bad news: RowHammer is getting worse
- **Good news: We have a lot more to do**
  - We are now fully aware hardware is easily fallible
  - We are developing both attacks and defenses
  - We are developing principled models, methodologies, solutions

# Industry's RowHammer Solutions (I)

---

SK hynix Semiconductor, Icheon, Korea

DRAM products have been recently adopted in a wide range of high-performance computing applications: such as in cloud computing, in big data systems, and IoT devices. This demand creates larger memory capacity requirements, thereby requiring aggressive DRAM technology node scaling to reduce the cost per bit [1,2]. However, DRAM manufacturers are facing technology scaling challenges due to row hammer and refresh retention time beyond 1a-nm [2]. Row hammer is a failure mechanism, where repeatedly activating a DRAM row disturbs data in adjacent rows. Scaling down severely threatens reliability since a reduction of DRAM cell size leads to a reduction in the intrinsic row hammer tolerance [2,3]. To improve row hammer tolerance, there is a need to probabilistically activate adjacent rows with carefully sampled active addresses and to improve intrinsic row hammer tolerance [2]. In this paper, row-hammer-protection and refresh-management schemes are presented to guarantee DRAM security and reliability despite the aggressive scaling from 1a-nm to sub 10-nm nodes. The probabilistic-aggressor-tracking scheme with a refresh-management function (RFM) and per-row hammer tracking (PRHT) improve DRAM resilience. A multi-step precharge reinforces intrinsic row-hammer tolerance and a core-bias modulation improves retention time: even in the face of cell-transistor degradation due to technology scaling. This comprehensive scheme leads to a reduced probability of failure, due to row hammer attacks, by 93.1% and an improvement in retention time by 17%.

Ramulator 2.0 is a modern, modular, extensible, and fast cycle-accurate DRAM simulator. It provides support for agile implementation and evaluation of new memory system designs (e.g., new DRAM standards, emerging RowHammer mitigation techniques). Described in our paper [https://people.inf.ethz.ch/omutlu/pub/Ramulator2\\_arxiv23.pdf](https://people.inf.ethz.ch/omutlu/pub/Ramulator2_arxiv23.pdf)
