An Intelligent Architecture Handles Data Well

How to Handle Data Well

- Ensure data does not overwhelm the components
 - via intelligent algorithms
 - via intelligent architectures
 - via whole system designs: algorithm-architecture-devices
- Take advantage of vast amounts of data and metadata
 - to improve architectural & system-level decisions
- Understand and exploit properties of (different) data
 - to improve algorithms & architectures in various metrics

Corollaries: Architectures Today ...

- Architectures are **terrible at dealing with data**
 - ❑ Designed to mainly store and move data vs. to compute
 - ❑ They are **processor-centric** as opposed to **data-centric**
- Architectures are **terrible at taking advantage of vast amounts of data** (and metadata) available to them
 - ❑ Designed to make simple decisions, ignoring lots of data
 - ❑ They make **human-driven decisions** vs. **data-driven**
- Architectures are **terrible at knowing and exploiting different properties of application data**
 - ❑ Designed to treat all data as the same
 - ❑ They make **component-aware decisions** vs. **data-aware**

Data-centric

Data-driven

Data-aware

We Need to Revisit the Entire Stack

We can get there step by step

To achieve the highest **energy efficiency** and **performance**:

we must take the expanded view
of computer architecture

Co-design across the hierarchy:
Algorithms to devices

Specialize as much as possible
within the design goals

Data-centric

Data-driven

Data-aware

Data-Centric (Memory-Centric) Architectures

Data-Centric Architectures: Properties

- **Process data where it resides** (where it makes sense)
 - Processing in and near memory structures
- **Low-latency and low-energy data access**
 - Low latency memory
 - Low energy memory
- **Low-cost data storage and processing**
 - High capacity memory at low cost: hybrid memory, compression
- **Intelligent data management**
 - Intelligent controllers handling robustness, security, cost

Processing Data Where It Makes Sense

Processing in/near Memory: An Old Idea

- Kautz, "Cellular Logic-in-Memory Arrays", IEEE TC 1969.

IEEE TRANSACTIONS ON COMPUTERS, VOL. C-18, NO. 8, AUGUST 1969

Cellular Logic-in-Memory Arrays

WILLIAM H. KAUTZ, MEMBER, IEEE

Abstract—As a direct consequence of large-scale integration, many advantages in the design, fabrication, testing, and use of digital circuitry can be achieved if the circuits can be arranged in a two-dimensional iterative, or cellular, array of identical elementary networks, or cells. When a small amount of storage is included in each cell, the same array may be regarded either as a logically enhanced memory array, or as a logic array whose elementary gates and connections can be "programmed" to realize a desired logical behavior.

In this paper the specific engineering features of such cellular logic-in-memory (CLIM) arrays are discussed, and one such special-purpose array, a cellular sorting array, is described in detail to illustrate how these features may be achieved in a particular design. It is shown how the cellular sorting array can be employed as a single-address, multiword memory that keeps in order all words stored within it. It can also be used as a content-addressed memory, a pushdown memory, a buffer memory, and (with a lower logical efficiency) a programmable array for the realization of arbitrary switching functions. A second version of a sorting array, operating on a different sorting principle, is also described.

Index Terms—Cellular logic, large-scale integration, logic arrays logic in memory, push-down memory, sorting, switching functions.

Fig. 1. Cellular sorting array I.

Processing in/near Memory: An Old Idea

- Stone, "A Logic-in-Memory Computer," IEEE TC 1970.

A Logic-in-Memory Computer

HAROLD S. STONE

Abstract—If, as presently projected, the cost of microelectronic arrays in the future will tend to reflect the number of pins on the array rather than the number of gates, the logic-in-memory array is an extremely attractive computer component. Such an array is essentially a microelectronic memory with some combinational logic associated with each storage element.

Why In-Memory Computation Today?

- Push from Technology
 - DRAM Scaling at jeopardy
 - Controllers close to DRAM
 - Industry open to new memory architectures

[†]Vrije Universiteit Amsterdam

A Single Bit-flip Can Cause Terminal Brain Damage to DNNs

One specific bit-flip in a DNN's representation leads to accuracy drop over 90%

Our research found that a specific bit-flip in a DNN's bitwise representation can cause the accuracy loss up to 90%, and the DNN has 40-50% parameters, on average, that can lead to the accuracy drop over 10% when individually subjected to such single bitwise corruptions...

Rowhammer

How Reliable/Secure/Safe is This Bridge?

Collapse of the “Galloping Gertie” (1940)

How Safe & Secure Is This Platform?

Security is about preventing unforeseen consequences

How Safe & Secure Is **This** Platform?

Computing Systems
Need

Intelligent Memories

In-Field Patch-ability
(Intelligent Memory)
Can Avoid Many Failures

Main Memory Needs Intelligent Controllers

Why In-Memory Computation Today?

- **Push from Technology**

- **DRAM Scaling at jeopardy**

- Controllers close to DRAM

- Industry open to new memory architectures

- **Pull from Systems and Applications**

- **Data access is a major system and application bottleneck**

- **Systems are energy limited**

- **Data movement much more energy-hungry than computation**

Three Key Systems & Application Trends

1. Data access is a major bottleneck

- ▣ Applications are increasingly data hungry

2. Energy consumption is a key limiter

3. Data movement energy dominates compute

- ▣ Especially true for off-chip to on-chip movement

Do We Want This?

Or This?

High Performance,
Energy Efficient,
Sustainable

The Problem

Data access is the major performance and energy bottleneck

Our current
design principles
cause great energy waste
(and great performance loss)

The Problem

Processing of data
is performed
far away from the data

A Computing System

- Three key components
- Computation
- Communication
- Storage/memory

Burks, Goldstein, von Neumann, "Preliminary discussion of the logical design of an electronic computing instrument," 1946.

A Computing System

- Three key components
- Computation
- Communication
- Storage/memory

Burks, Goldstein, von Neumann, "Preliminary discussion of the logical design of an electronic computing instrument," 1946.

Computing System

Today's Computing Systems

- Are overwhelmingly processor centric
- All data processed in the processor → at great system cost
- Processor is heavily optimized and is considered the master
- Data storage units are dumb and are largely unoptimized (except for some that are on the processor die)

Yet ...

I expect that over the coming decade memory subsystem design will be the *only* important design issue for microprocessors.

- **“It’s the Memory, Stupid!”** (Richard Sites, MPR, 1996)

The Performance Perspective

The Performance Perspective (Today)

- All of Google's Data Center Workloads (2015):

Figure 11: Half of cycles are spent stalled on caches.

Perils of Processor-Centric Design

■ Grossly-imbalanced systems

- ❑ Processing done only in **one place**
- ❑ Everything else just stores and moves data: **data moves a lot**
 - Energy inefficient
 - Low performance
 - Complex

■ Overly complex and bloated processor (and accelerators)

- ❑ To tolerate data access from memory
- ❑ Complex hierarchies and mechanisms
 - Energy inefficient
 - Low performance
 - Complex

Perils of Processor-Centric Design

Most of the system is dedicated to storing and moving data

Yet, system is still bottlenecked by memory

The Energy Perspective

Communication Dominates Arithmetic

Dally, HiPEAC 2015

Data Movement vs. Computation Energy

Communication Dominates Arithmetic

Dally, HiPEAC 2015

A memory access consumes $\sim 100-1000X$ the energy of a complex addition

Data Movement vs. Computation Energy

- **Data movement** is a major system energy bottleneck
 - ❑ Comprises 41% of mobile system energy during web browsing [2]
 - ❑ Costs ~ 115 times as much energy as an ADD operation [1, 2]

[1]: Reducing data Movement Energy via Online Data Clustering and Encoding (MICRO'16)

[2]: Quantifying the energy cost of data movement for emerging smart phone workloads on mobile platforms (IISWC'14)

Energy Waste in Mobile Devices

Abstract

Modern computing systems are overwhelmingly designed to move data to computation. This design choice goes directly against at least three key trends in computing that cause performance, scalability and energy bottlenecks: (1) data access is a key bottleneck as many important applications are increasingly data-intensive, and memory bandwidth and energy do not scale well, (2) energy consumption is a key limiter in almost all computing platforms, especially server and mobile systems, (3) data movement, especially off-chip to on-chip, is very expensive in terms of bandwidth, energy and latency, much more so than computation. These trends are especially severely-felt in the data-intensive server and energy-constrained mobile systems of today.

At the same time, conventional memory technology is facing many technology scaling challenges in terms of reliability, energy, and performance. As a result, memory system architects are open to organizing memory in different ways and making it more intelligent, at the expense of higher cost. The emergence of 3D-stacked memory plus logic, the adoption of error correcting codes inside the latest DRAM chips, proliferation of different main memory standards and chips, specialized for different purposes (e.g., graphics, low-power, high bandwidth, low latency), and the necessity of designing new solutions to serious reliability and security issues, such as the RowHammer phenomenon, are an evidence of this trend.

This chapter discusses recent research that aims to practically enable computation close to data, an approach we call *processing-in-memory* (PIM). PIM places computation mechanisms in or near where the data is stored (i.e., inside the memory chips, in the logic layer of 3D-stacked memory, or in the memory controllers), so that data movement between the computation units and memory is reduced or eliminated. While the general idea of PIM is not new, we discuss motivating trends in applications as well as memory circuits/technology that greatly exacerbate the need for enabling it in modern computing systems. We examine at least two promising new approaches to designing PIM systems to accelerate important data-intensive applications: (1) *processing using memory* by exploiting analog operational properties of DRAM chips to perform massively-parallel operations in memory, with low-cost changes, (2) *processing near memory* by exploiting 3D-stacked memory technology design to provide high memory bandwidth and low memory latency to in-memory logic. In both approaches, we describe and tackle relevant cross-layer research, design, and adoption challenges in devices, architecture, systems, and programming models. Our focus is on the development of in-memory processing designs that can be adopted in real computing platforms at low cost. We conclude by discussing work on solving key challenges to the practical adoption of PIM.

Main memory, built using the Dynamic Random Access Memory (DRAM) technology, is a major component in nearly all computing systems, including servers, cloud platforms, mobile/embedded devices, and sensor systems. Across all of these systems, the data working set sizes of modern applications are rapidly growing, while the need for fast analysis of such data is increasing. Thus, main memory is becoming an increasingly significant bottleneck across a wide variety of computing systems and applications [1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16]. Alleviating the main memory bottleneck requires the memory capacity, energy, cost, and performance to all scale in an efficient manner across technology generations. Unfortunately, it has become increasingly difficult in recent years, especially the past decade, to scale all of these dimensions [1, 2, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49], and thus the main memory bottleneck has been worsening.

A major reason for the main memory bottleneck is the high energy and latency cost associated with *data movement*. In modern computers, to perform any operation on data that resides in main memory, the processor must retrieve the data from main memory. This requires the memory controller to issue commands to a DRAM module across a relatively slow and power-hungry off-chip bus (known as the *memory channel*). The DRAM module sends the requested data across the memory channel, after which the data is placed in the caches and registers. The CPU can perform computation on the data once the data is in its registers. Data movement from the DRAM to the CPU incurs long latency and consumes a significant amount of energy [7, 50, 51, 52, 53, 54]. These costs are often exacerbated by the fact that much of the data brought into the caches is *not reused* by the CPU [52, 53, 55, 56], providing little benefit in return for the high latency and energy cost.

The cost of data movement is a fundamental issue with the *processor-centric* nature of contemporary computer systems. The CPU is considered to be the master in the system, and computation is performed only in the processor (and accelerators). In contrast, data storage and communication units, including the main memory, are treated as unintelligent workers that are incapable of computation. As a result of this processor-centric design paradigm, data moves a lot in the system between the computation units and communication/ storage units so that computation can be done on it. With the increasingly *data-centric* nature of contemporary and emerging appli-

We Need to Think Differently
from the Past Approaches

Processing in Memory: Two Approaches

1. Processing using Memory
2. Processing near Memory

Two PIM Approaches

5.2. Two Approaches: Processing Using Memory (PUM) vs. Processing Near Memory (PNM)

Many recent works take advantage of the memory technology innovations that we discuss in Section 5.1 to enable and implement PIM. We find that these works generally take one of two approaches, which are categorized in Table 1: (1) *processing using memory* or (2) *processing near memory*. We briefly describe each approach here. Sections 6 and 7 will provide example approaches and more detail for both.

Table 1: Summary of enabling technologies for the two approaches to PIM used by recent works. Adapted from [309].

Approach	Enabling Technologies
Processing Using Memory	SRAM
	DRAM
	Phase-change memory (PCM)
	Magnetic RAM (MRAM)
Processing Near Memory	Resistive RAM (RRAM)/memristors
	Logic layers in 3D-stacked memory
	Silicon interposers
	Logic in memory controllers

Processing using memory (PUM) exploits the existing memory architecture and the operational principles of the memory circuitry to enable operations within main memory with minimal changes. PUM makes use

Lecture on RowClone & Processing using DRAM

Mindset: Memory as an Accelerator

The diagram illustrates a system architecture where memory is treated as an accelerator. On the left, a large gray box represents the system, containing several components: four 'CPU core' blocks, one 'mini-CPU core', one 'video core', one 'imaging core', and four 'GPU (throughput) core' blocks. Below these is a large 'LLC' (Last Level Cache) block, which is connected to a 'Memory Controller' block. The 'Memory Controller' is connected to a 'Memory Bus'. To the right of the system box is a large 'Memory' block. A red rounded rectangle highlights a 'Specialized compute-capability in memory' block within the memory, which is also connected to the 'Memory Bus'. A video player interface is overlaid on the bottom of the diagram, showing a red text overlay: 'Memory similar to a "conventional" accelerator'. The video player also shows a progress bar at 43:48 / 2:03:45 and various control icons.

Executive Summary

Context: We extensively analyze a state-of-the-art edge ML accelerator (Google Edge TPU) using 24 Google edge models

- Wide range of models (CNNs, LSTMs, Transducers, RCNNs)

Problem: The Edge TPU accelerator suffers from **three challenges:**

- It operates **significantly below** its peak throughput
- It operates **significantly below** its theoretical energy efficiency
- It **inefficiently** handles memory accesses

Key Insight: These shortcomings arise from **the monolithic design** of the Edge TPU accelerator

- The Edge TPU accelerator design does not account for **layer heterogeneity**

Key Mechanism: A new framework called **Mensa**

- Mensa consists of heterogeneous accelerators whose dataflow and hardware are specialized for specific families of layers

Key Results: We design a version of Mensa for Google edge ML models

- Mensa improves performance and energy by **3.0X** and **3.1X**
- Mensa reduces cost and improves area efficiency

Mensa: Highly-Efficient ML Inference

Abstract

Modern computing systems are overwhelmingly designed to move data to computation. This design choice goes directly against at least three key trends in computing that cause performance, scalability and energy bottlenecks: (1) data access is a key bottleneck as many important applications are increasingly data-intensive, and memory bandwidth and energy do not scale well, (2) energy consumption is a key limiter in almost all computing platforms, especially server and mobile systems, (3) data movement, especially off-chip to on-chip, is very expensive in terms of bandwidth, energy and latency, much more so than computation. These trends are especially severely-felt in the data-intensive server and energy-constrained mobile systems of today.

At the same time, conventional memory technology is facing many technology scaling challenges in terms of reliability, energy, and performance. As a result, memory system architects are open to organizing memory in different ways and making it more intelligent, at the expense of higher cost. The emergence of 3D-stacked memory plus logic, the adoption of error correcting codes inside the latest DRAM chips, proliferation of different main memory standards and chips, specialized for different purposes (e.g., graphics, low-power, high bandwidth, low latency), and the necessity of designing new solutions to serious reliability and security issues, such as the RowHammer phenomenon, are an evidence of this trend.

This chapter discusses recent research that aims to practically enable computation close to data, an approach we call *processing-in-memory* (PIM). PIM places computation mechanisms in or near where the data is stored (i.e., inside the memory chips, in the logic layer of 3D-stacked memory, or in the memory controllers), so that data movement between the computation units and memory is reduced or eliminated. While the general idea of PIM is not new, we discuss motivating trends in applications as well as memory circuits/technology that greatly exacerbate the need for enabling it in modern computing systems. We examine at least two promising new approaches to designing PIM systems to accelerate important data-intensive applications: (1) *processing using memory* by exploiting analog operational properties of DRAM chips to perform massively-parallel operations in memory, with low-cost changes, (2) *processing near memory* by exploiting 3D-stacked memory technology design to provide high memory bandwidth and low memory latency to in-memory logic. In both approaches, we describe and tackle relevant cross-layer research, design, and adoption challenges in devices, architecture, systems, and programming models. Our focus is on the development of in-memory processing designs that can be adopted in real computing platforms at low cost. We conclude by discussing work on solving key challenges to the practical adoption of PIM.

Main memory, built using the Dynamic Random Access Memory (DRAM) technology, is a major component in nearly all computing systems, including servers, cloud platforms, mobile/embedded devices, and sensor systems. Across all of these systems, the data working set sizes of modern applications are rapidly growing, while the need for fast analysis of such data is increasing. Thus, main memory is becoming an increasingly significant bottleneck across a wide variety of computing systems and applications [1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16]. Alleviating the main memory bottleneck requires the memory capacity, energy, cost, and performance to all scale in an efficient manner across technology generations. Unfortunately, it has become increasingly difficult in recent years, especially the past decade, to scale all of these dimensions [1, 2, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49], and thus the main memory bottleneck has been worsening.

A major reason for the main memory bottleneck is the high energy and latency cost associated with *data movement*. In modern computers, to perform any operation on data that resides in main memory, the processor must retrieve the data from main memory. This requires the memory controller to issue commands to a DRAM module across a relatively slow and power-hungry off-chip bus (known as the *memory channel*). The DRAM module sends the requested data across the memory channel, after which the data is placed in the caches and registers. The CPU can perform computation on the data once the data is in its registers. Data movement from the DRAM to the CPU incurs long latency and consumes a significant amount of energy [7, 50, 51, 52, 53, 54]. These costs are often exacerbated by the fact that much of the data brought into the caches is *not reused* by the CPU [52, 53, 55, 56], providing little benefit in return for the high latency and energy cost.

The cost of data movement is a fundamental issue with the *processor-centric* nature of contemporary computer systems. The CPU is considered to be the master in the system, and computation is performed only in the processor (and accelerators). In contrast, data storage and communication units, including the main memory, are treated as unintelligent workers that are incapable of computation. As a result of this processor-centric design paradigm, data moves a lot in the system between the computation units and communication/ storage units so that computation can be done on it. With the increasingly *data-centric* nature of contemporary and emerging appli-

 ONUR MUTLU, ETH Zürich, Switzerland

Many modern workloads, such as neural networks, databases, and graph processing, are fundamentally memory-bound. For such workloads, the data movement between main memory and CPU cores imposes a significant overhead in terms of both latency and energy. A major reason is that this communication happens through a narrow bus with high latency and limited bandwidth, and the low data reuse in memory-bound workloads is insufficient to amortize the cost of main memory access. Fundamentally addressing this *data movement bottleneck* requires a paradigm where the memory system assumes an active role in computing by integrating processing capabilities. This paradigm is known as *processing-in-memory (PIM)*.

Recent research explores different forms of PIM architectures, motivated by the emergence of new 3D-stacked memory technologies that integrate memory with a logic layer where processing elements can be easily placed. Past works evaluate these architectures in simulation or, at best, with simplified hardware prototypes. In contrast, the UPMEM company has designed and manufactured the first publicly-available real-world PIM architecture. The UPMEM PIM architecture combines traditional DRAM memory arrays with general-purpose in-order cores, called *DRAM Processing Units (DPUs)*, integrated in the same chip.

This paper provides the first comprehensive analysis of the first publicly-available real-world PIM architecture. We make two key contributions. First, we conduct an experimental characterization of the UPMEM-based PIM system using microbenchmarks to assess various architecture limits such as compute throughput and memory bandwidth, yielding new insights. Second, we present *PrIM (Processing-In-Memory benchmarks)*, a benchmark suite of 16 workloads from different application domains (e.g., dense/sparse linear algebra, databases, data analytics, graph processing, neural networks, bioinformatics, image processing), which we identify as memory-bound. We evaluate the performance and scaling characteristics of PrIM benchmarks on the UPMEM PIM architecture, and compare their performance and energy consumption to their state-of-the-art CPU and GPU counterparts. Our extensive evaluation conducted on two real UPMEM-based PIM systems with 640 and 2,560 DPUs provides new insights about suitability of different workloads to the PIM system, programming recommendations for software designers, and suggestions and hints for hardware and architecture designers of future PIM systems.

PrIM (Processing-In-Memory Benchmarks)

PrIM is the first benchmark suite for a real-world processing-in-memory (PIM) architecture. PrIM is developed to evaluate, analyze, and characterize the first publicly-available real-world processing-in-memory (PIM) architecture, the [UPMEM](#) PIM architecture. The UPMEM PIM architecture combines traditional DRAM memory arrays with general-purpose in-order cores, called DRAM Processing Units (DPUs), integrated in the same chip.

PrIM provides a common set of workloads to evaluate the UPMEM PIM architecture with and can be useful for programming, architecture and system researchers all alike to improve multiple aspects of future PIM hardware and software. The workloads have different characteristics, exhibiting heterogeneity in their memory access patterns, operations and data types, and communication patterns. This repository also contains baseline CPU and GPU implementations of PrIM benchmarks for comparison purposes.

PrIm also includes a set of microbenchmarks can be used to assess various architecture limits such as compute throughput and memory bandwidth.

Inter-DPU Communication

- There is **no direct communication channel between DPUs**

- Inter-DPU communication takes place via the host CPU using CPU-DPU and DPU-CPU transfers
- Example communication patterns:
 - Merging of partial results to obtain the final result
 - Only DPU-CPU transfers
 - Redistribution of intermediate results for further computation
 - DPU-CPU transfers and CPU-DPU transfers

Data movement between the CPU and main memory is a first-order obstacle against improving performance, scalability, and energy efficiency in modern systems. Computer systems employ a range of techniques to reduce overheads tied to data movement, spanning from traditional mechanisms (e.g., deep multi-level cache hierarchies, aggressive hardware prefetchers) to emerging techniques such as Near-Data Processing (NDP), where some computation is moved close to memory. Prior NDP works investigate the root causes of data movement bottlenecks using different profiling methodologies and tools. However, there is still a lack of understanding about the key metrics that can identify different data movement bottlenecks and their relation to traditional and emerging data movement mitigation mechanisms. Our goal is to methodically identify potential sources of data movement over a broad set of applications and to comprehensively compare traditional compute-centric data movement mitigation techniques (e.g., caching and prefetching) to more memory-centric techniques (e.g., NDP), thereby developing a rigorous understanding of the best techniques to mitigate each source of data movement.

With this goal in mind, we perform the first large-scale characterization of a wide variety of applications, across a wide range of application domains, to identify fundamental program properties that lead to data movement to/from main memory. We develop the first systematic methodology to classify applications based on the sources contributing to data movement bottlenecks. From our large-scale characterization of 77K functions across 345 applications, we select 144 functions to form the first open-source benchmark suite (DAMOV) for main memory data movement studies. We select a diverse range of functions that (1) represent different types of data movement bottlenecks, and (2) come from a wide range of application domains. Using NDP as a case study, we identify new insights about the different data movement bottlenecks and use these insights to determine the most suitable data movement mitigation mechanism for a particular application. We open-source DAMOV and the complete source code for our new characterization methodology at <https://github.com/CMU-SAFARI/DAMOV>.

When to Employ Near-Data Processing?

DAMOV: A New Methodology and Benchmark Suite for Evaluating Data Movement Bottlenecks

DAMOV is a benchmark suite and a methodical framework targeting the study of data movement bottlenecks in modern applications. It is intended to study new architectures, such as near-data processing.

The DAMOV benchmark suite is the first open-source benchmark suite for main memory data movement-related studies, based on our systematic characterization methodology. This suite consists of 144 functions representing different sources of data movement bottlenecks and can be used as a baseline benchmark set for future data-movement mitigation research. The applications in the DAMOV benchmark suite belong to popular benchmark suites, including [BWA](#), [Chai](#), [Darknet](#), [GASE](#), [Hardware Effects](#), [Hashjoin](#), [HPCC](#), [HPCG](#), [Ligra](#), [PARSEC](#), [Parboil](#), [PolyBench](#), [Phoenix](#), [Rodinia](#), [SPLASH-2](#), [STREAM](#).

Samsung Function-in-Memory DRAM (2021)

Samsung Develops Industry's First High Bandwidth Memory with AI Processing Power

Korea on February 17, 2021

Audio

Share

The new architecture will deliver over twice the system performance and reduce energy consumption by more than 70%

Samsung Electronics, the world leader in advanced memory technology, today announced that it has developed the industry's first High Bandwidth Memory (HBM) integrated with artificial intelligence (AI) processing power – the HBM-PIM. The new processing-in-memory (PIM) architecture brings powerful AI computing capabilities inside high-performance memory, to accelerate large-scale processing in data centers, high performance computing (HPC) systems and AI-enabled mobile applications.

Kwangil Park, senior vice president of Memory Product Planning at Samsung Electronics stated, "Our groundbreaking HBM-PIM is the industry's first programmable PIM solution tailored for diverse AI-driven workloads such as HPC, training and inference. We plan to build upon this breakthrough by further collaborating with AI solution providers for even more advanced PIM-powered applications."

EDIT VIDEO

<https://www.youtube.com/onurmutlulectures>

Concluding Remarks

Recap: Corollaries: Architectures Today

- Architectures are **terrible at dealing with data**
 - ❑ Designed to mainly store and move data vs. to compute
 - ❑ They are **processor-centric** as opposed to **data-centric**
- Architectures are **terrible at taking advantage of vast amounts of data** (and metadata) available to them
 - ❑ Designed to make simple decisions, ignoring lots of data
 - ❑ They make **human-driven decisions** vs. **data-driven**
- Architectures are **terrible at knowing and exploiting different properties of application data**
 - ❑ Designed to treat all data as the same
 - ❑ They make **component-aware decisions** vs. **data-aware**

Concluding Remarks

- It is time to design **principled system architectures** to solve the **data handling** (i.e., memory/storage) problem
- Design complete systems to be truly balanced, high-performance, and **energy-efficient** → intelligent systems
 - ❑ **Data-centric, data-driven, data-aware**
- Enable computation capability inside and close to memory
- **This** can
 - ❑ Lead to **orders-of-magnitude** improvements
 - ❑ **Enable new applications & computing platforms**
 - ❑ **Enable better understanding of nature**
 - ❑ ...

Data-centric

Data-driven

Data-aware

We Need to Revisit the Entire Stack

We can get there step by step

We Need to Exploit Good Principles

- Data-centric system design
- All components intelligent
- Better cross-layer communication, better interfaces
- Better-than-worst-case design
- Heterogeneity
- Flexibility, adaptability

Open minds

Abstract

Modern computing systems are overwhelmingly designed to move data to computation. This design choice goes directly against at least three key trends in computing that cause performance, scalability and energy bottlenecks: (1) data access is a key bottleneck as many important applications are increasingly data-intensive, and memory bandwidth and energy do not scale well, (2) energy consumption is a key limiter in almost all computing platforms, especially server and mobile systems, (3) data movement, especially off-chip to on-chip, is very expensive in terms of bandwidth, energy and latency, much more so than computation. These trends are especially severely-felt in the data-intensive server and energy-constrained mobile systems of today.

At the same time, conventional memory technology is facing many technology scaling challenges in terms of reliability, energy, and performance. As a result, memory system architects are open to organizing memory in different ways and making it more intelligent, at the expense of higher cost. The emergence of 3D-stacked memory plus logic, the adoption of error correcting codes inside the latest DRAM chips, proliferation of different main memory standards and chips, specialized for different purposes (e.g., graphics, low-power, high bandwidth, low latency), and the necessity of designing new solutions to serious reliability and security issues, such as the RowHammer phenomenon, are an evidence of this trend.

This chapter discusses recent research that aims to practically enable computation close to data, an approach we call *processing-in-memory* (PIM). PIM places computation mechanisms in or near where the data is stored (i.e., inside the memory chips, in the logic layer of 3D-stacked memory, or in the memory controllers), so that data movement between the computation units and memory is reduced or eliminated. While the general idea of PIM is not new, we discuss motivating trends in applications as well as memory circuits/technology that greatly exacerbate the need for enabling it in modern computing systems. We examine at least two promising new approaches to designing PIM systems to accelerate important data-intensive applications: (1) *processing using memory* by exploiting analog operational properties of DRAM chips to perform massively-parallel operations in memory, with low-cost changes, (2) *processing near memory* by exploiting 3D-stacked memory technology design to provide high memory bandwidth and low memory latency to in-memory logic. In both approaches, we describe and tackle relevant cross-layer research, design, and adoption challenges in devices, architecture, systems, and programming models. Our focus is on the development of in-memory processing designs that can be adopted in real computing platforms at low cost. We conclude by discussing work on solving key challenges to the practical adoption of PIM.

Keywords: memory systems, data movement, main memory, processing-in-memory, near-data processing, computation-in-memory, processing using memory, processing near memory, 3D-stacked memory, non-volatile memory, energy efficiency, high-performance computing, computer architecture, computing paradigm, emerging technologies, memory scaling, technology scaling, dependable systems, robust systems, hardware security, system security, latency, low-latency computing

9 Conclusion and Future Outlook	31

Main memory, built using the Dynamic Random Access Memory (DRAM) technology, is a major component in nearly all computing systems, including servers, cloud platforms, mobile/embedded devices, and sensor systems. Across all of these systems, the data working set sizes of modern applications are rapidly growing, while the need for fast analysis of such data is increasing. Thus, main memory is becoming an increasingly significant bottleneck across a wide variety of computing systems and applications [1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16]. Alleviating the main memory bottleneck requires the memory capacity, energy, cost, and performance to all scale in an efficient manner across technology generations. Unfortunately, it has become increasingly difficult in recent years, especially the past decade, to scale all of these dimensions [1, 2, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49], and thus the main memory bottleneck has been worsening.

A major reason for the main memory bottleneck is the high energy and latency cost associated with *data movement*. In modern computers, to perform any operation on data that resides in main memory, the processor must retrieve the data from main memory. This requires the memory controller to issue commands to a DRAM module across a relatively slow and power-hungry off-chip bus (known as the *memory channel*). The DRAM module sends the requested data across the memory channel, after which the data is placed in the caches and registers. The CPU can perform computation on the data once the data is in its registers. Data movement from the DRAM to the CPU incurs long latency and consumes a significant amount of energy [7, 50, 51, 52, 53, 54]. These costs are often exacerbated by the fact that much of the data brought into the caches is *not reused* by the CPU [52, 53, 55, 56], providing little benefit in return for the high latency and energy cost.

The cost of data movement is a fundamental issue with the *processor-centric* nature of contemporary computer systems. The CPU is considered to be the master in the system, and computation is performed only in the processor (and accelerators). In contrast, data storage and communication units, including the main memory, are treated as unintelligent workers that are incapable of computation. As a result of this processor-centric design paradigm, data moves a lot in the system between the computation units and communication/ storage units so that computation can be done on it. With the increasingly *data-centric* nature of contemporary and emerging appli-

Data-Driven Architectures

Corollaries: Architectures Today ...

- Architectures are **terrible at dealing with data**
 - ❑ Designed to mainly store and move data vs. to compute
 - ❑ They are **processor-centric** as opposed to **data-centric**
- Architectures are **terrible at taking advantage of vast amounts of data** (and metadata) available to them
 - ❑ Designed to make simple decisions, ignoring lots of data
 - ❑ They make **human-driven decisions** vs. **data-driven** decisions
- Architectures are **terrible at knowing and exploiting different properties of application data**
 - ❑ Designed to treat all data as the same
 - ❑ They make **component-aware decisions** vs. **data-aware**

Exploiting Data to Design Intelligent Architectures

System Architecture Design Today

- Human-driven
 - Humans design the policies (how to do things)
- Many (too) simple, short-sighted policies all over the system
- No automatic data-driven policy learning
- (Almost) no learning: cannot take lessons from past actions

**Can we design
fundamentally intelligent architectures?**

An Intelligent Architecture

- Data-driven
 - Machine learns the “best” policies (how to do things)
- Sophisticated, workload-driven, changing, far-sighted policies
- Automatic data-driven policy learning
- All controllers are intelligent data-driven agents

How do we start?

Self-Optimizing Memory Controllers

Memory Controller

How to schedule requests to maximize system performance?

Why are Memory Controllers Difficult to Design?

- Need to obey **DRAM timing constraints** for correctness
 - There are many (50+) timing constraints in DRAM
 - tWTR: Minimum number of cycles to wait before issuing a read command after a write command is issued
 - tRC: Minimum number of cycles between the issuing of two consecutive activate commands to the same bank
 - ...
- Need to **keep track of many resources** to prevent conflicts
 - Channels, banks, ranks, data bus, address bus, row buffers, ...
- Need to handle **DRAM refresh**
- Need to **manage power** consumption
- Need to **optimize performance & QoS** (in the presence of constraints)
 - Reordering is not simple
 - Fairness and QoS needs complicates the scheduling problem
- ...

Many Memory Timing Constraints

Latency	Symbol	DRAM cycles	Latency	Symbol	DRAM cycles
Precharge	t_{RP}	11	Activate to read/write	t_{RCD}	11
Read column address strobe	CL	11	Write column address strobe	CWL	8
Additive	AL	0	Activate to activate	t_{RC}	39
Activate to precharge	t_{RAS}	28	Read to precharge	t_{RTP}	6
Burst length	t_{BL}	4	Column address strobe to column address strobe	t_{CCD}	4
Activate to activate (different bank)	t_{RRD}	6	Four activate windows	t_{FAW}	24
Write to read	t_{WTR}	6	Write recovery	t_{WR}	12

Table 4. DDR3 1600 DRAM timing specifications

Figure 5. Three Phases of DRAM Access

Table 2. Timing Constraints (DDR3-1066) [43]

Phase	Commands	Name	Value
1	ACT → READ	tRCD	15ns
	ACT → WRITE		
	ACT → PRE	tRAS	37.5ns
2	READ → data	tCL	15ns
	WRITE → data	tCWL	11.25ns
	data burst	tBL	7.5ns
3	PRE → ACT	tRP	15ns
1 & 3	ACT → ACT	tRC (tRAS+tRP)	52.5ns

Memory Controller Design Is Becoming More Difficult

- Heterogeneous agents: CPUs, GPUs, and HWAs
- Main memory interference between CPUs, GPUs, HWAs
- Many timing constraints for various memory types
- Many goals at the same time: performance, fairness, QoS, energy efficiency, ...

Reality and Dream

- **Reality**: It difficult to design a policy that maximizes performance, QoS, energy-efficiency, ...
 - ❑ Too many things to think about
 - ❑ Continuously changing workload and system behavior

- **Dream**: Wouldn't it be nice if the DRAM controller automatically found a good scheduling policy on its own?

Self-Optimizing DRAM Controllers

- Problem: DRAM controllers are difficult to design
 - It is difficult for human designers to design a policy that can adapt itself very well to different workloads and different system conditions
- Idea: A memory controller that adapts its scheduling policy to workload behavior and system conditions using machine learning.
- Observation: Reinforcement learning maps nicely to memory control.
- Design: Memory controller is a reinforcement learning agent
 - It dynamically and continuously learns and employs the best scheduling policy to maximize long-term performance.

Self-Optimizing DRAM Controllers

Goal: Learn to choose actions to maximize $r_0 + \gamma r_1 + \gamma^2 r_2 + \dots$ ($0 \leq \gamma < 1$)

Figure 2: (a) Intelligent agent based on reinforcement learning principles;

Self-Optimizing DRAM Controllers

- Dynamically adapt the memory scheduling policy via interaction with the system at runtime
 - Associate system states and actions (commands) with long term reward values: **each action at a given state leads to a learned reward**
 - **Schedule command with highest estimated long-term reward value in each state**
 - **Continuously update reward values for $\langle \text{state}, \text{action} \rangle$ pairs based on feedback from system**

Self-Optimizing DRAM Controllers

Proceedings of the 35th International Symposium on Computer Architecture (ISCA), pages 39-50, Beijing, China, June 2008.

Figure 4: High-level overview of an RL-based scheduler.

States, Actions, Rewards

❖ Reward function

- +1 for scheduling Read and Write commands
- 0 at all other times

Goal is to maximize long-term data bus utilization

❖ State attributes

- Number of reads, writes, and load misses in transaction queue
- Number of pending writes and ROB heads waiting for referenced row
- Request's relative ROB order

❖ Actions

- Activate
- Write
- Read - load miss
- Read - store miss
- Precharge - pending
- Precharge - preemptive
- NOP

Performance Results

Figure 7: Performance comparison of in-order, FR-FCFS, RL-based, and optimistic memory controllers

Large, robust performance improvements over many human-designed policies

Figure 15: Performance comparison of FR-FCFS and RL-based memory controllers on systems with 6.4GB/s and 12.8GB/s peak DRAM bandwidth

Self Optimizing DRAM Controllers

- + Continuous learning in the presence of changing environment

- + Reduced designer burden in finding a good scheduling policy.

Designer specifies:

- 1) What system variables might be useful

- 2) What target to optimize, but not how to optimize it

- How to specify different objectives? (e.g., fairness, QoS, ...)

- Hardware complexity?

- Design mindset and flow

Pythia

A Customizable Hardware Prefetching Framework Using Online Reinforcement Learning

Rahul Bera, Konstantinos Kanellopoulos, Anant V. Nori,
Taha Shahroodi, Sreenivas Subramoney, Onur Mutlu

<https://github.com/CMU-SAFARI/Pythia>

Executive Summary

- **Background:** Prefetchers predict addresses of future memory requests by associating memory access patterns with program context (called **feature**)
- **Problem:** Three key shortcomings of prior prefetchers:
 - Predict mainly using a **single program feature**
 - Lack **inherent system awareness** (e.g., memory bandwidth usage)
 - Lack **in-silicon customizability**
- **Goal:** Design a prefetching framework that:
 - Learns from **multiple features** and **inherent system-level feedback**
 - Can be **customized in silicon** to use different features and/or prefetching objectives
- **Contribution:** Pythia, which formulates prefetching as reinforcement learning problem
 - Takes **adaptive** prefetch decisions using multiple features and system-level feedback
 - Can be **customized in silicon** for target workloads via simple configuration registers
 - Proposes **a realistic and practical** implementation of RL algorithm in hardware
- **Key Results:**
 - Evaluated using a wide range of workloads from SPEC CPU, PARSEC, Ligra, Cloudsuite
 - Outperforms best prefetcher (in 1-core config.) by **3.4%, 7.7% and 17%** in 1/4/bw-constrained cores
 - Up to **7.8% more performance** over basic Pythia across Ligra workloads via simple customization

Key Shortcomings in Prior Prefetchers

- We observe **three key shortcomings** that significantly limit performance benefits of prior prefetchers

1 Predict mainly using a **single program feature**

2 Lack inherent **system awareness**

3 Lack **in-silicon customizability**

Our Goal

A **prefetching framework** that can:

1. Learn to prefetch using **multiple features** and **inherent system-level feedback** information
2. Be **easily customized in silicon** to use different features and/or change prefetcher's objectives

Our Proposal

Pythia

Formulates prefetching as a
reinforcement learning problem

Basics of Reinforcement Learning (RL)

- Algorithmic approach to learn to take an **action** in a given **situation** to maximize a numerical **reward**

Agent

Environment

- Agent stores **Q-values** for *every* state-action pair
 - **Expected return** for taking an action in a state
 - Given a state, selects action that provides **highest** Q-value

Formulating Prefetching as RL

Pythia Overview

- **Q-Value Store**: Records Q-values for *all* state-action pairs
- **Evaluation Queue**: A FIFO queue of recently-taken actions

Simulation Methodology

- **Champsim** [3] trace-driven simulator
- **150** single-core memory-intensive workload traces
 - SPEC CPU2006 and CPU2017
 - PARSEC 2.1
 - Ligra
 - Cloudsuite
- Homogeneous and heterogeneous multi-core mixes
- **Five** state-of-the-art prefetchers
 - SPP [Kim+, MICRO'16]
 - Bingo [Bakhshalipour+, HPCA'19]
 - MLOP [Shakerinava+, 3rd Prefetching Championship, 2019]
 - SPP+DSPatch [Bera+, MICRO'19]
 - SPP+PPF [Bhatia+, ISCA'20]

Basic Pythia Configuration

- Derived from **automatic design-space exploration**
- **State:** 2 features
 - PC+Delta
 - Sequence of last-4 deltas
- **Actions:** 16 prefetch offsets
 - Ranging between -6 to +32. Including 0.
- **Rewards:**
 - $R_{AT} = +20$; $R_{AL} = +12$; $R_{NP-H} = -2$; $R_{NP-L} = -4$;
 - $R_{IN-H} = -14$; $R_{IN-L} = -8$; $R_{CL} = -12$

Performance with Varying Core Count

Performance with Varying Core Count

The graph shows performance on the y-axis (ranging from 1.1 to 1.35) against the number of cores on the x-axis (ranging from 0 to 12). Pythia (red line) starts at ~1.28 at 2 cores, peaks at ~1.32 at 4 cores, and then declines. Other models (blue, green, orange lines) show lower performance, with a green line showing a 3.4% gain at 8 cores. A vertical green line at 12 cores is labeled 'SDD'.

1. Pythia consistently provides the highest performance in **all core configurations**

2. Pythia's gain **increases with core count**

Performance with Varying DRAM Bandwidth

Performance with Varying DRAM Bandwidth

Pythia outperforms prior best prefetchers for a wide range of DRAM bandwidth configurations

Pythia's Overhead

- **25.5 KB** of total metadata storage **per core**
 - Only simple tables
- We also model functionally-accurate Pythia with full complexity in **Chisel** [4] HDL

1.03% area overhead

0.4% power overhead

Satisfies prediction latency

of a desktop-class 4-core Skylake processor (Xeon D2132IT, 60W)

More in the Paper

- Performance comparison with **unseen traces**
 - Pythia provides equally high performance benefits

• Comparison against **multi-level prefetchers**

An Intelligent Architecture

- Data-driven
 - Machine learns the “best” policies (how to do things)
- Sophisticated, workload-driven, changing, far-sighted policies
- Automatic data-driven policy learning
- All controllers are intelligent data-driven agents

**We need to rethink design
(of all controllers)**

Data-Driven **(Self-Optimizing)** **Computing Architectures**

Data-Aware Architectures

Corollaries: Architectures Today ...

- Architectures are **terrible at dealing with data**
 - ❑ Designed to mainly store and move data vs. to compute
 - ❑ They are **processor-centric** as opposed to **data-centric**
- Architectures are **terrible at taking advantage of vast amounts of data** (and metadata) available to them
 - ❑ Designed to make simple decisions, ignoring lots of data
 - ❑ They make **human-driven decisions** vs. **data-driven** decisions
- Architectures are **terrible at knowing and exploiting different properties of application data**
 - ❑ Designed to treat all data as the same
 - ❑ They make **component-aware decisions** vs. **data-aware**

Data-Aware Architectures

- A data-aware architecture understands what it can do with and to each piece of data
- It makes use of different properties of data to improve performance, efficiency and other metrics
 - Compressibility
 - Approximability
 - Locality
 - Sparsity
 - Criticality for Computation X
 - Access Semantics
 - ...

One Problem: Limited Expressiveness

Higher-level information is not visible to HW

A Solution: More Expressive Interfaces

Performance

[§]ETH Zürich

SW provides key program information to HW

Broader goal: Enable many cross-layer optimizations

Express:

Data structures

Access semantics

Data types

Working set

Reuse

Access frequency

...

Optimizations:

Cache Management

Data Placement in DRAM

Data Compression

Approximation

DRAM Cache Management

NVM Management

NUCA/NUMA

Optimizations

...

Benefits:

More efficient HW:

✓ **Performance**

**Reduced SW
burden:**

✓ **Programmability**

✓ **Portability**

Our approach: Rich cross-layer abstractions

1. **Generality:** Enable a wide range of cross-layer approaches
2. **Minimize programmer effort**
3. **Overhead**

Approach: Flexibly associate specific semantic information with any **data & code**

Example: XMem

- **Goal:** convey data semantics to the hardware enables more intelligent management of resources.
- **XMem:** introduces a new HW/SW abstraction, called *Atom*, for conveying data semantics

XMem Aids/Enables Many Optimizations

Table 1: Summary of the example memory optimizations that XMem aids.

Memory optimization	Example semantics provided by XMem (described in §3.3)	Example Benefits of XMem
Cache management	(i) Distinguishing between data structures or pools of similar data; (ii) Working set size; (iii) Data reuse	Enables: (i) applying different caching policies to different data structures or pools of data; (ii) avoiding cache thrashing by <i>knowing</i> the active working set size; (iii) bypassing/prioritizing data that has no/high reuse. (§5)
Page placement in DRAM e.g., [23, 24]	(i) Distinguishing between data structures; (ii) Access pattern; (iii) Access intensity	Enables page placement at the <i>data structure</i> granularity to (i) isolate data structures that have high row buffer locality and (ii) spread out concurrently-accessed irregular data structures across banks and channels to improve parallelism. (§6)
Cache/memory compression e.g., [25–32]	(i) Data type: integer, float, char; (ii) Data properties: sparse, pointer, data index	Enables using a <i>different compression algorithm</i> for each data structure based on data type and data properties, e.g., sparse data encodings, FP-specific compression, delta-based compression for pointers [27].
Data prefetching e.g., [33–36]	(i) Access pattern: strided, irregular, irregular but repeated (e.g., graphs), access stride; (ii) Data type: index, pointer	Enables (i) <i>highly accurate</i> software-driven prefetching while leveraging the benefits of hardware prefetching (e.g., by being memory bandwidth-aware, avoiding cache thrashing); (ii) using different prefetcher <i>types</i> for different data structures: e.g., stride [33], tile-based [20], pattern-based [34–37], data-based for indices/pointers [38, 39], etc.
DRAM cache management e.g., [40–46]	(i) Access intensity; (ii) Data reuse; (iii) Working set size	(i) Helps avoid cache thrashing by knowing working set size [44]; (ii) Better DRAM cache management via reuse behavior and access intensity information.
Approximation in memory e.g., [47–53]	(i) Distinguishing between pools of similar data; (ii) Data properties: tolerance towards approximation	Enables (i) each memory component to track how approximable data is (at a fine granularity) to inform approximation techniques; (ii) data placement in heterogeneous reliability memories [54].
Data placement: NUMA systems e.g., [55, 56]	(i) Data partitioning across threads (i.e., relating data to threads that access it); (ii) Read-Write properties	Reduces the need for profiling or data migration (i) to co-locate data with threads that access it and (ii) to identify Read-Only data, thereby enabling techniques such as replication.
Data placement: hybrid memories e.g., [16, 57, 58]	(i) Read-Write properties (Read-Only/Read-Write); (ii) Access intensity; (iii) Data structure size; (iv) Access pattern	Avoids the need for profiling/migration of data in hybrid memories to (i) effectively manage the asymmetric read-write properties in NVM (e.g., placing Read-Only data in the NVM) [16, 57]; (ii) make tradeoffs between data structure "hotness" and size to allocate fast/high bandwidth memory [14]; and (iii) leverage row-buffer locality in placement based on access pattern [45].
Managing NUCA systems e.g., [15, 59]	(i) Distinguishing pools of similar data; (ii) Access intensity; (iii) Read-Write or Private-Shared properties	(i) Enables using different cache policies for different data pools (similar to [15]); (ii) Reduces the need for reactive mechanisms that detect sharing and read-write characteristics to inform cache policies.

Data-Aware Cross-Layer Hybrid System Management

- Heterogeneous agents: CPUs, GPUs, and HWAs
- Main memory interference between CPUs, GPUs, HWAs
- Many timing constraints for various memory types
- Many goals at the same time: performance, fairness, QoS, energy efficiency, ...

Another Example: EDEN for DNNs

- Deep Neural Network evaluation is very DRAM-intensive (especially for large networks)
1. Some data and layers in DNNs are very tolerant to errors
 2. Reduce DRAM latency and voltage on such data and layers
 3. While still achieving a user-specified DNN accuracy target by making training DRAM-error-aware

Data-aware management of DRAM latency and voltage for Deep Neural Network Inference

Example DNN Data Type to DRAM Mapping

Mapping example of ResNet-50:

Map more error-tolerant DNN layers
to DRAM partitions with lower voltage/latency

4 DRAM partitions with different error rates

EDEN: Overview

Key idea: Enable **accurate, efficient** DNN inference using **approximate DRAM**

EDEN is an **iterative** process that has **3 key steps**

CPU: DRAM Energy Evaluation

Average 21% DRAM energy reduction
maintaining accuracy within 1% of original

CPU: Performance Evaluation

Average 8% system speedup
Some workloads achieve **17% speedup**

EDEN achieves **close to the ideal** speedup
possible via tRCD scaling

GPU, Eyeriss, and TPU: Energy Evaluation

- GPU: average **37% energy reduction**
- Eyeriss: average **31% energy reduction**
- TPU: average **32% energy reduction**

Data-Aware (Expressive)

Computing Architectures

We Need to **Rethink** the Entire Stack

We can get there case by case

Principled Architectures & What They Can Enable

A Quote from A Famous Architect

- “architecture [...] based upon **principle**, and not upon **precedent**”

Precedent-Based Design?

- “architecture [...] based upon **principle**, and not upon **precedent**”

Principled Design

- “architecture [...] based upon **principle**, and not upon **precedent**”

The Overarching Principle

Organic architecture

From Wikipedia, the free encyclopedia

Organic architecture is a [philosophy](#) of [architecture](#) which promotes harmony between human habitation and the natural world through design approaches so sympathetic and well integrated with its site, that buildings, furnishings, and surroundings become part of a unified, interrelated composition.

A well-known example of organic architecture is [Fallingwater](#), the residence Frank Lloyd Wright designed for the Kaufmann family in rural Pennsylvania. Wright had many choices to locate a home on this large site, but chose to place the home directly over the waterfall and creek creating a close, yet noisy dialog with the rushing water and the steep site. The horizontal striations of stone masonry with daring [cantilevers](#) of colored beige concrete blend with native rock outcroppings and the wooded environment.

Another Example: Precedent-Based Design

Principled Design

Another Principled Design

Source: <http://www.arcspace.com/exhibitions/unsorted/santiago-calatrava/>

Another Principled Design

Principle Applied to Another Structure

Source: By 準建築人手札網站 Forgemind ArchiMedia - Flickr: IMG_2489.JPG, CC BY 2.0

Source: <https://www.dezeen.com/2016/08/29/santiago-calatrava-oculus-world-trade-center-transportation-hub-new-york-photographs-hufton-crow/>
<https://commons.wikimedia.org/wiki/index.php?curid=91498936>, https://en.wikipedia.org/wiki/Santiago_Calatrava

The Overarching Principle

Zoomorphic architecture

From Wikipedia, the free encyclopedia

Zoomorphic architecture is the practice of using animal forms as the inspirational basis and blueprint for architectural design. "While animal forms have always played a role adding some of the deepest layers of meaning in architecture, it is now becoming evident that a new strand of **biomorphism** is emerging where the meaning derives not from any specific representation but from a more general allusion to biological processes."^[1]

Some well-known examples of Zoomorphic architecture can be found in the **TWA Flight Center** building in **New York City**, by **Eero Saarinen**, or the **Milwaukee Art Museum** by **Santiago Calatrava**, both inspired by the form of a bird's wings.^[3]

Overarching Principles for Computing?

Readings, Videos, Reference Materials

More on My Research & Teaching

Brief Self Introduction

■ Onur Mutlu

- ❑ Full Professor @ ETH Zurich ITET (INFK), since September 2015
- ❑ Strecker Professor @ Carnegie Mellon University ECE/CS, 2009-2016, 2016-...
- ❑ PhD from UT-Austin, worked at Google, VMware, Microsoft Research, Intel, AMD
- ❑ <https://people.inf.ethz.ch/omutlu/>
- ❑ omutlu@gmail.com (Best way to reach me)
- ❑ <https://people.inf.ethz.ch/omutlu/projects.htm>

■ Research and Teaching in:

- ❑ Computer architecture, computer systems, hardware security, bioinformatics
- ❑ Memory and storage systems
- ❑ Hardware security, safety, predictability
- ❑ Fault tolerance
- ❑ Hardware/software cooperation
- ❑ Architectures for bioinformatics, health, medicine
- ❑ ...

Current Research Mission

Computer architecture, HW/SW, systems, bioinformatics, security

Build fundamentally better architectures

Four Key Current Directions

- Fundamentally Secure/Reliable/Safe Architectures
- Fundamentally Energy-Efficient Architectures
 - Memory-centric (Data-centric) Architectures
- Fundamentally Low-Latency and Predictable Architectures
- Architectures for AI/ML, Genomics, Medicine, Health

The Transformation Hierarchy

To achieve the highest **energy efficiency** and **performance**:

we must take the expanded view
of computer architecture

Co-design across the hierarchy:
Algorithms to devices

Specialize as much as possible
within the design goals

Current Research Mission & Major Topics

Build fundamentally better architectures

**Broad research
spanning apps, systems, logic
with architecture at the center**

- Data-centric arch. for low energy & high perf.
 - Proc. in Mem/DRAM, NVM, unified mem/storage
- Low-latency & predictable architectures
 - Low-latency, low-energy yet low-cost memory
 - QoS-aware and predictable memory systems
- Fundamentally secure/reliable/safe arch.
 - Tolerating all bit flips; patchable HW; secure mem
- Architectures for ML/AI/Genomics/Health/Med
 - Algorithm/arch./logic co-design; full heterogeneity
- Data-driven and data-aware architectures
 - ML/AI-driven architectural controllers and design
 - Expressive memory and expressive systems

SAFARI Research Group

Newsletter
January 2021

*Think Big, Aim High, and
Have a Wonderful 2021!*

Dear SAFARI friends,

Happy New Year! We are excited to share our group highlights with you in this second edition of the SAFARI newsletter (You can find the first edition from April 2020 [here](#)). 2020 has

SAFARI PhD and Post-Doc Alumni

- <https://safari.ethz.ch/safari-alumni/>
- Minesh Patel (ETH Zurich), MICRO 2020 and DSN 2020 Best Paper Awards; ISCA Hall of Fame 2021
- Damla Senol Cali (Bionano Genomics), SRC TECHCON 2019 Best Student Presentation Award
- Nastaran Hajinazar (ETH Zurich)
- Gagandeep Singh (ETH Zurich), FPL 2020 Best Paper Award Finalist
- Amirali Boroumand (Stanford Univ → Google), SRC TECHCON 2018 Best Student Presentation Award
- Jeremie Kim (ETH Zurich), EDAA Outstanding Dissertation Award 2020; IEEE Micro Top Picks 2019; ISCA/MICRO HoF 2021
- Nandita Vijaykumar (Univ. of Toronto, Assistant Professor), ISCA Hall of Fame 2021
- Kevin Hsieh (Microsoft Research, Senior Researcher)
- Justin Meza (Facebook), HiPEAC 2015 Best Student Presentation Award; ICCD 2012 Best Paper Award
- Mohammed Alser (ETH Zurich), IEEE Turkey Best PhD Thesis Award 2018
- Yixin Luo (Google), HPCA 2015 Best Paper Session
- Kevin Chang (Facebook), SRC TECHCON 2016 Best Student Presentation Award
- Rachata Ausavarungrun (KMUNTB, Assistant Professor), NOCS 2015 and NOCS 2012 Best Paper Award Finalist
- Gennady Pekhimenko (Univ. of Toronto, Assistant Professor), ISCA Hall of Fame 2021; ASPLOS 2015 SRC Winner
- Vivek Seshadri (Microsoft Research)
- Donghyuk Lee (NVIDIA Research, Senior Researcher), HPCA Hall of Fame 2018
- Yoongu Kim (Software Robotics → Google), TCAD'19 Top Pick Award; IEEE Micro Top Picks'10; HPCA'10 Best Paper Session
- Lavanya Subramanian (Intel Labs → Facebook)
- Samira Khan (Univ. of Virginia, Assistant Professor), HPCA 2014 Best Paper Session
- Saugata Ghose (Univ. of Illinois, Assistant Professor), DFRWS-EU 2017 Best Paper Award
- Jawad Haj-Yahya (Huawei Research Zurich, Principal Researcher)

Principle: Teaching and Research

...

Teaching drives Research

Research drives Teaching

...

Principle: Learning and Scholarship

Focus on
learning and scholarship

Principle: Insight and Ideas

Focus on Insight

Encourage New Ideas

Principle: Learning and Scholarship

The quality of your work
defines your impact

Principle: Good Mindset, Goals & Focus

You can make a
good impact
on the world

SAFARI Projects & Seminars Courses (Spring 2021)

Welcome to the wiki for Project and Seminar courses SAFARI offers.

Courses we offer:

- Understanding and Improving Modern DRAM Performance, Reliability, and Security with Hands-On Experiments
- Designing and Evaluating Memory Systems and Modern Software Workloads with Ramulator
- Accelerating Genome Analysis with FPGAs, GPUs, and New Execution Paradigms
- Genome Sequencing on Mobile Devices
- Exploring the Processing-in-Memory Paradigm for Future Computing Systems
- Hands-on Acceleration on Heterogeneous Computing Systems
- Understanding and Designing Modern NAND Flash-Based Solid-State Drives (SSDs) by Building a Practical SSD Simulator

Data-Centric and Data-Aware Frameworks for Fundamentally Efficient Data Handling in Modern Computing Systems

SAFARI
SAFARI Research Group

27 Wed Oct 2021

Overview of Our Approach

Data and the **efficient computation of data** should be the ultimate priority of the system

- **Data-Centric Architectures**
 - Enable computation with minimal data movement
 - Compute where data resides
- **Data-Aware Architectures**
 - Understand what they can do with and to each piece of data
 - Make use of different properties of data to improve performance, efficiency, etc.

Accelerating Genome Sequence Analysis via Efficient Hardware/Algorithm Co-Design

SAFARI
SAFARI Research Group

7 Sun Nov 2021

Our Goal & Approach

- **Our Goal:**
Accelerating genome sequence analysis by **efficient hardware/algorithm co-design**
- **Our Approach:**
 - (1) Analyze the **multiple steps** and the **associated tools** in the genome sequence analysis pipeline,
 - (2) Expose the **tradeoffs** between accuracy, performance, memory usage and scalability, and
 - (3) Co-design **fast and efficient algorithms** along with **scalable and energy-efficient customized hardware accelerators** for the key bottleneck steps of the pipeline

A Talk on Impactful Research & Teaching

The video player shows a presentation slide with the title "Applying to Grad School & Doing Impactful Research" in a green serif font, enclosed in a thin gold border. Below the title, the speaker's name "Onur Mutlu" is listed, followed by his email "omutlu@gmail.com" and a URL "https://people.inf.ethz.ch/omutlu". The date "13 June 2020" and the event "Undergraduate Architecture Mentoring Workshop @ ISCA 2021" are also displayed. At the bottom of the slide, the logos for "SAFARI", "ETH zürich", and "Carnegie Mellon" are shown. The video player interface includes a progress bar at 0:27 / 50:31, a small video feed of the speaker in the top right corner, and a bottom bar with engagement metrics (74 likes, 1 comment), share options, and buttons for "ANALYTICS" and "EDIT VIDEO".

Fundamental Thinking

Historical: Opportunities at the Bottom

There's Plenty of Room at the Bottom

From Wikipedia, the free encyclopedia

"There's Plenty of Room at the Bottom: An Invitation to Enter a New Field of Physics" was a lecture given by [physicist Richard Feynman](#) at the annual [American Physical Society](#) meeting at [Caltech](#) on December 29, 1959.^[1] Feynman considered the possibility of direct manipulation of individual atoms as a more powerful form of synthetic chemistry than those used at the time. Although versions of the talk were reprinted in a few popular magazines, it went largely unnoticed and did not inspire the conceptual beginnings of the field. Beginning in the 1980s, nanotechnology advocates cited it to establish the scientific credibility of their work.

Historical: Opportunities at the Bottom (II)

There's Plenty of Room at the Bottom

From Wikipedia, the free encyclopedia

Feynman considered some ramifications of a general ability to manipulate matter on an atomic scale. He was particularly interested in the possibilities of denser computer circuitry, and microscopes that could see things much smaller than is possible with scanning electron microscopes. These ideas were later realized by the use of the scanning tunneling microscope, the atomic force microscope and other examples of scanning probe microscopy and storage systems such as Millipede, created by researchers at IBM.

Feynman also suggested that it should be possible, in principle, to make nanoscale machines that "arrange the atoms the way we want", and do chemical synthesis by mechanical manipulation.

He also presented the possibility of "swallowing the doctor", an idea that he credited in the essay to his friend and graduate student Albert Hibbs. This concept involved building a tiny, swallowable surgical robot.

Historical: Opportunities at the Top

REVIEW

There's plenty of room at the Top: What will drive computer performance after Moore's law?

 Charles E. Leiserson¹,  Neil C. Thompson^{1,2,*},  Joel S. Emer^{1,3},  Bradley C. Kuszmaul^{1,†}, Butler W. Lampson^{1,4},  ...

+ See all authors and affiliations

Science 05 Jun 2020:
Vol. 368, Issue 6495, eaam9744
DOI: 10.1126/science.aam9744

Much of the improvement in computer performance comes from decades of miniaturization of computer components, a trend that was foreseen by the Nobel Prize-winning physicist Richard Feynman in his 1959 address, “There’s Plenty of Room at the Bottom,” to the American Physical Society. In 1975, Intel founder Gordon Moore predicted the regularity of this miniaturization trend, now called Moore’s law, which, until recently, doubled the number of transistors on computer chips every 2 years.

Unfortunately, semiconductor miniaturization is running out of steam as a viable way to grow computer performance—there isn’t much more room at the “Bottom.” If growth in computing power stalls, practically all industries will face challenges to their productivity. Nevertheless, opportunities for growth in computing performance will still be available, especially at the “Top” of the computing-technology stack: software, algorithms, and hardware architecture.

Axiom, Revisited

There **is** plenty of room both at the top and at the bottom

but **much more so**

when you

communicate well between and optimize across

the top and the bottom

Hence the Expanded View

**Computer Architecture
(expanded view)**

Data-centric

Data-driven

Data-aware
